The Town of East Gwillimbury

Stormwater Management Master Plan Municipal Class Environmental Assessment

W10-487

November 2012

COLE ENGINEERING

Experience Enhancing Excellence

Executive Summary

Introduction

The Town of East Gwillimbury (the Town, "Owner") has retained Cole Engineering Group Ltd. (Cole Engineering) to prepare a Stormwater Management Master Plan (SWMMP) in accordance to the Lake Simcoe Protection Plan 2009 by the Province of Ontario, through Phases 1 and 2 of a Master Plan Municipal Class Environmental Assessment (Class EA). The Town is located just south of Lake Simcoe and is bound by the Town of Georgina to the north, the Regional Municipality of Durham to the east, the Town of Newmarket and Town of Whitchurch-Stouffville to the south and the Township of King and County of Simcoe to the west. The study area is approximately 25,000 hectares (62,000 acres) and is mainly rural with the exception of the community villages of Holland Landing, Queensville, Sharon, Green Lane West and Mount Albert. The Town drains to four (4) subwatersheds: Black River subwatershed, Maskinonge River subwatershed, East Holland River subwatershed, and West Holland River subwatershed. Parts of the Greenbelt and the Oak Ridges Moraine are within the Town boundary but are mostly outside of the main settlement areas. There are existing Stormwater Management (SWM) works in place that consist of dry and wet ponds. The intent of the SWMMP is to develop the practical and implementable framework which balances the requirements of proposed and existing development with infrastructure requirements, economic, social and environmental constraints and opportunities.

SWMMP Plan Strategy

The objectives of the SWMMP is to investigate opportunities to prevent flooding, mitigate changes in water balance and reduce phosphorus loadings to Lake Simcoe, as well assess erosion issues and maintain / improve water quality. The report examines the existing environmental characteristics of the Town, land use changes, peak flow impacts, phosphorus loadings, water budget, and erosion analysis. Cole Engineering has also evaluated the potential impacts of climate change by developing a sensitivity analysis. Based on the results of each analysis, recommendations and the preferred alternative were developed for each settlement area. In addition, recommended SWM guidelines were established for future development within the Town.

An assessment of stormwater peak flows was conducted from existing and future conditions to evaluate the environmental impact of the future development in the Town. Subcatchment areas within the Town settlement areas were modelled under the 2 to 100-year storm events. Results indicate a general increase in peak flow as a result of the development proposed from the Official Plan. The current "post-to-pre" approach in terms of stormwater quantity control was applied to post-development drainage areas subject to increases in imperviousness from the future conditions model. As such, several drainage areas are required to be overcontrolled to unit flow control criteria in the event the "post-to pre" approach was not sufficient. This scenario was mostly evident in the East and West Holland River subwatersheds where development has been intensified. It is recommended however, that the "post-to-pre" approach be continued to be imposed for new development in the Black River and Maskinonge River where most peak flows are reduced. It is recommended that a detailed unit flow study is to be investigated (specifically within the Holland River) and implemented in the future.

A comparison of phosphorus loadings is required to assess the environmental impact of development in terms of phosphorus on Lake Simcoe. All settlement areas are expected to see an increase in phosphorus loads as development increases. An integrated treatment train approach is recommended to mitigate the accumulation of phosphorus from proposed development (i.e. bioretention, infiltration trenches, permeable pavement, and perforated pipe systems). It is noted that specific mitigation measures to be used to reduce phosphorus accumulation are to be confirmed on a site specific basis at the functional design stages of development.

A water balance assessment was developed as a part of the study to establish the infiltration deficit as a result of future development. Soil type along with land use was utilized to calculate water balance for the pre and post development conditions. On an individual settlement basis an infiltration rate was formulated based on post development infiltration rates. Results of the analysis indicate that due to soil restrictions and land constraints, the use of Best Management Practices were recommended where applicable on a site specific basis (i.e. soakaway pits, bioretention, infiltration trenches and chambers, permeable pavement, and grassed swales).

Erosion analysis was based on the current creek survey data developed by the LSRCA in 2008. Most concern was due to stream bank erosion, sediment build up in the watercourses, and unrestricted livestock access. Traditional BMP measures, bank stabilization and riparian vegetation are recommended to decrease sedimentation and reduce flows. A detailed erosion analysis of creeks within the Town did not take place as a part of this study and the Town is recommended to investigate the opportunity for individual erosion assessments where future development will take place.

A sensitivity analysis was conducted to determine the potential impacts of climate change. Although the definition of climate change is still undefined, Cole Engineering has developed hydrologic models to determine the impacts on existing stormwater management facilities (SWMFs) if the effects of change would increase / decrease rainfall intensity, increase / decrease storm duration and under the application of wet and dry soil conditions. The results indicate that the changes in the conditions of storm events and hydrologic parameters on the existing SWMFs in the Town are generally sensitive in terms of peak outflows and storage volumes. A number of assumptions were made in regards to the effects of climate change on SWM and it is recommended that further study be developed to accurately assess climate change impacts.

As part of this project a software tool called SWMSoft has been utilized to develop an inventory of all the existing SWMFs. With the use of this program, a maintenance schedule has been established to allow for all facilities to meet current Enhanced standards. The Town will be able to use this software to determine when facilities will need to be retrofitted and an approximate cost of the work needed. There are currently four (4) SWM ponds that are required to be tended to immediately in order to meet standards.

Public Information Centre / Stakeholder Consultation

A notice of commencement and notice of Public Information Centre (PIC) were completed as part of this study and were posted on the “Our Town News” section of the Town’s website and published in the Town’s newspaper, the Era Banner. In addition, the notices were mailed directly to affected stakeholders.

One (1) Public Information Centre (PIC) took place during the project. The PIC was held on March 3, 2011 to present the alternative strategies identified. It was attended by six (6) people mostly consisting of Town Council and Staff. The Project Team including representatives from Cole Engineering and the Town were in attendance to answer any questions that participants had.

The PIC presented the following elements:

- Study Overview & Background;
- Problem / Opportunity Statement;
- Overview of the Municipal Class Environmental Assessment Process;
- Alternative Solutions Being Considered; and,
- Next Steps.

No comments were received from public consultation and a notice of completion of this project is targeted at the second quarter of 2011.

SWM Recommendations

Future SWMFs will be designed to Ministry of the Environment (MOE) standards:

- Stormwater Quality Control: Enhanced – 80% TSS removal, 80% TP removal;
- Stormwater Quantity Control: Post-development peak flows to be reduced to pre-development levels for all storm events up to and including the 100-year storm. Unit-flow rates are to be applied for specific drainage areas requiring over-control to meet pre-development peak flows; **
- The Regional Storm should be controlled to the pre-development peak flow rate level *if* noted in the subwatershed study (LSRCA Technical Guidelines for Stormwater Management Submissions, November 2010);
- Site specific erosion control and detention time calculations based on individual fluvial assessment of the receiving stream (i.e. 24hr, 48hr, 72hr, etc.);
- Future developments will follow the guidelines as outlined in the Lake Simcoe Protection Plan (LSPP);
- BMPs will be implemented where applicable to establish a treatment train approach (i.e. source, conveyance and end-of-pipe treatment);
- Where opportunities exist, implement enhanced vegetation for shading, bottom draw outlets, cooling trenches at SWMF locations to reduce stormwater temperature;
- Where opportunities exist, reduce phosphorus discharge, improve infiltration and reduce erosion potential within settlement areas and expansion of settlement area boundaries;
- Where opportunities exist, implement rural retrofits for applicable areas outside of existing settlement boundaries; and,
- Proceed with retrofit opportunities and maintenance operations of select SWM facilities as identified by the LSRCA and the SWM Master Plan.

** It is recommended that an investigation regarding the implementation of unit flow criteria should be conducted in the future for the East and West Holland River subwatersheds to establish a reduction of peak flows.

Preferred Alternative

The preferred alternative in each settlement area is the Traditional SWM with BMP Implementation Strategy. Based on the future land use, the preferred alternative is to be combined with Traditional SWM with Urban or Rural Retrofits Strategy. The proposed BMP implementation and Urban / Rural Retrofits will be determined on a site specific basis at the functional design stages of development.

LIST OF TABLES

APPENDICES

1.0 Introduction

1.1. Background

In November 2010, the Town of East Gwillimbury (the Town, "Owner") initiated a "Master Plan" Municipal Class Environmental Assessment (Class EA) to develop plans and strategies to govern the Stormwater Management (SWM) and practices within the Town limits. The intent of the Stormwater Management Master Plan (SWMMP) is to prepare a practical and implementable framework which balances the requirements of proposed and existing development with infrastructure requirements, economic, social and environmental constraints and opportunities. The Lake Simcoe Protection Plan was introduced by the Province of Ontario in June of 2009, and it called for all settlement areas to prepare and implement comprehensive SWMMP that would improve the management of stormwater for both existing and planned development. This report is prepared in the spirit of the Comprehensive Stormwater Management Master Plan Guidelines as well as with the Class EA which is described further in **Section 2.0**.

1.2. Location

The Town is located just south of Lake Simcoe and is bounded by the Town of Georgina to the north, the Regional Municipality of Durham to the east, the Town of Newmarket and the Town of Whitchurch-Stouffville to the south and the Township of King and County of Simcoe to the west. The study area is approximately 25,000 hectares (62,000 acres) and is mainly rural with the exception of the community villages of Holland Landing, Queensville, Sharon, Green Lane West and Mount Albert. The study area is illustrated below in **Figure 1-1**.

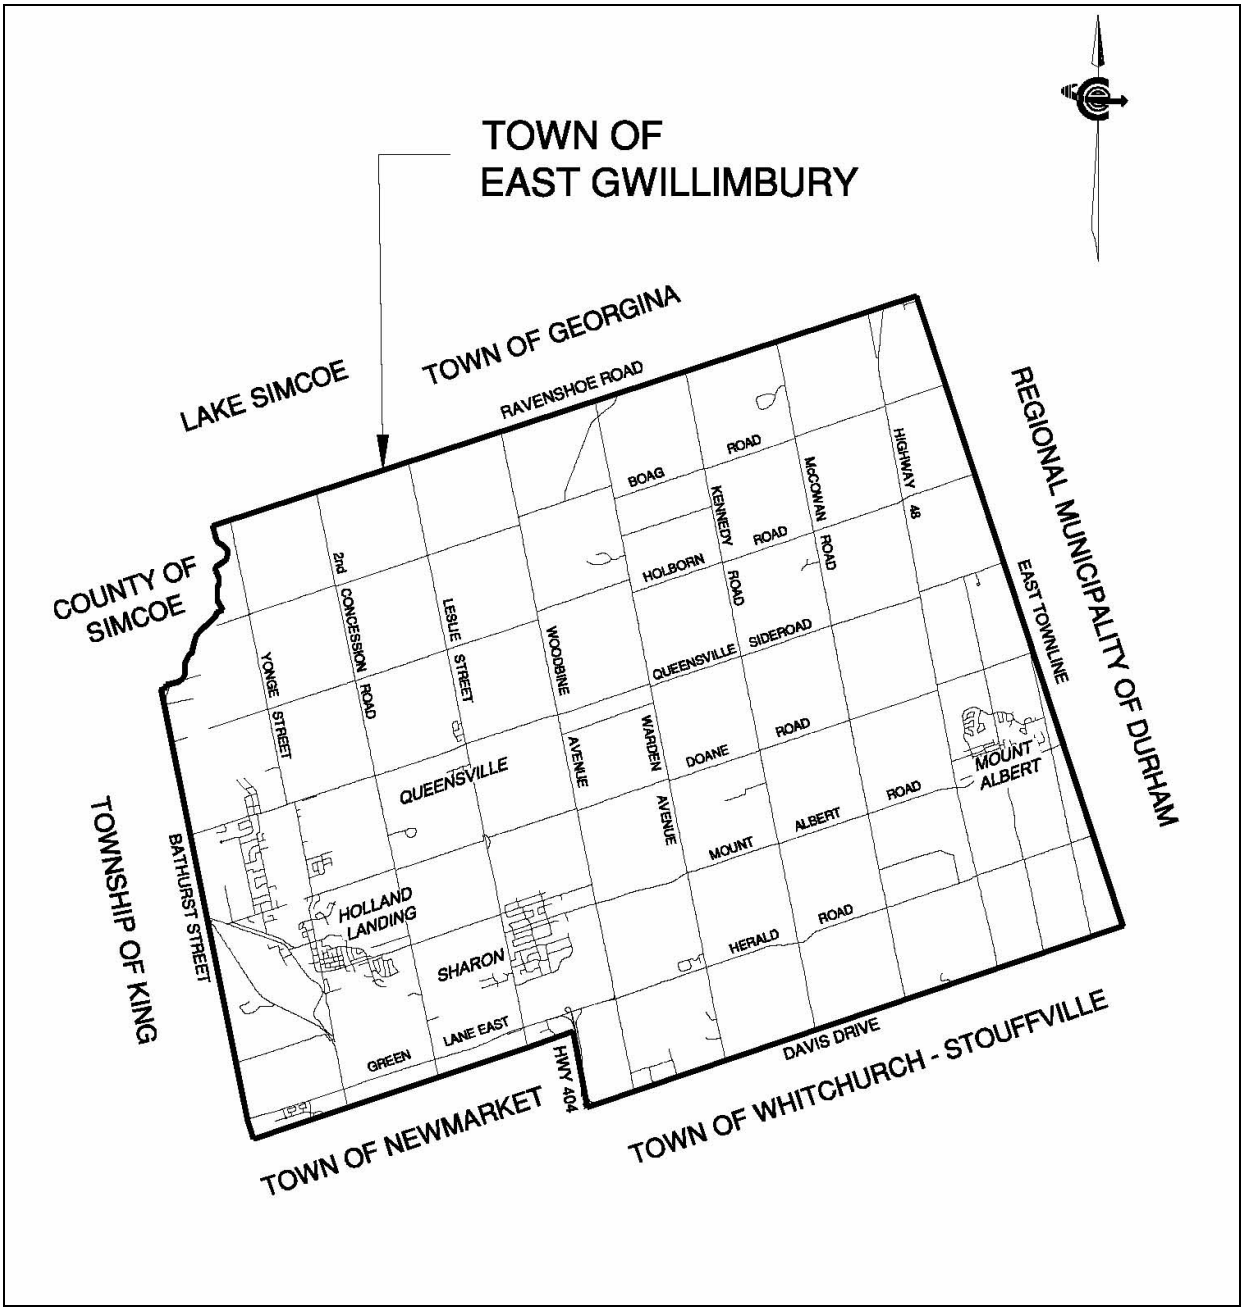

Figure 1-1 – Study Area

1.3. Study Overview

In 2010, the Town developed a Consolidated Official Plan (OP) Document outlining the proposed developments and standards to the year 2031. The OP's purpose is to provide direction and a policy framework for managing growth and land use decisions over the proposed planning period. It is expected that the Town will grow in population from 23,000 to 86,400 residents and the planned policy is to ensure appropriate growth towards a sustainable community. The Town's Thinking Green! Sustainability Strategy and Development Standards provides a foundation and guiding objectives for the policy and framework of the official plan. The five (5) pillars of the Strategic Plan adopted by the Town in 2005 outline the Council's vision for the future.

The five (5) pillars are as follows:

1. Protecting and Enhancing the Natural Environment;
2. Providing and Advocating for Quality Programs and Services to the Community;
3. Investing in Municipal Infrastructure;
4. Managing Growth to Ensure a Sustainable Community; and,
5. Supporting a Municipal Organization Focused on Excellence.
6. The Town's consolidated OP will provide a framework for the development of the SWMMP and outline existing constraints and opportunities for the implementation of SWM for existing and planned developments.

The Town is part of four (4) major subwatersheds within the Lake Simcoe Watershed:

1. The West Holland;
2. East Holland;
3. Maskinonge River; and,
4. Black River sub-watersheds.

The main drainage sheds are the Black River and East Holland River and the associated tributaries which ultimately drain to Lake Simcoe. The subwatershed boundaries and existing subcatchment areas are illustrated below in **Figure 1-2**.

1.4. Previous Studies

A number of previous studies have been developed within the study area.

These studies include:

- Queensville Community Master Plan Volume II – Master Drainage Plan - Town of East Gwillimbury, revised June 2000;
- Sharon Community OPA – 55 SWM Study - Town of East Gwillimbury, revised June 2005;
- Sharon Community Plan Master Environmental and Servicing Plan – MMM Group, February 2010;
- Growth Plan for the Greater Golden Horseshoe – Ministry of Public Infrastructure Renewal, 2006;
- Report on the Phosphorus Loads to Lake Simcoe – Lake Simcoe Conservation Authority, 2004-2007;
- Lake Simcoe Basin SWM and Retrofit Opportunities – Lake Simcoe Conservation Authority, 2007;
- Hydrology Report (Final) – Hydrologic and Hydraulic Modeling for the West Holland River, East Holland River and Maskinonge River Watersheds, CCL, June 30, 2005;
- Hydraulic Report (Final) – Hydrologic and Hydraulic Modeling for the West Holland River, East Holland River and Maskinonge River Watersheds, CCL, July 11, 2005;
- Black River Hydraulic Model Update – Completed as part of the Regulation Limit Mapping, LSRCA, 2005;
- West Holland River Subwatershed Plan – Lake Simcoe Region Conservation Authority, 2010;
- East Holland River Subwatershed Plan – Lake Simcoe Region Conservation Authority, 2010;
- Maskinonge River Subwatershed Plan – Lake Simcoe Region Conservation Authority, 2010; and,
- Black River Subwatershed Plan – Lake Simcoe Region Conservation Authority, 2010.

Key aspects of existing master plans within the Town are summarized below.

1.4.1. Queensville Community Master Plan, June 2000

Recommended Master SWM Plan Practices:

- General surface storage, vegetative, soft measures, special purpose and conservation / restoration classes to address stormwater quality concerns;
- Other management concerns pertaining to erosion control, water quantity control, and groundwater recharge impacts;
- Conveyance – dual drainage principle (minor and major stormwater drainage systems), 5 year flow;
- Lot Level Controls – Drainage swales, Dry swales (Soakaway Pits), Reduced Lot Grading to Maximize depression storage for groundwater recharge; and,

- End-of-pipe – Off-line SWMFs (provide water quality, erosion, quantity control), on-line SWMFs, on-site detention (industrial blocks), OGS, phosphorus control, Enhanced control.

Design Guidelines:

- Water Quality – Based on aquatic life, Enhanced (80% TSS Removal);
- Water Quantity – No increases to peak flow above pre-development level, where possible 10-15% over control;
- Erosion Control – storage of first flush (25mm rainfall volume 2-hour duration) for 24 hours; and,
- Infiltration encouraged.

It should be noted that the Queensville Community Master Plan (June 2000) was completed before the implementation of the Lake Simcoe Protection Plan (2009).

1.4.2. Sharon Community Plan – Master Environmental Servicing Plan (MESP), February 2010

Design Guidelines:

- Storm drainage conveyance system will be dual drainage (major and minor);
- Pipes will be sized to accommodate flows from a 1 in 5 year event at or below 90% of pipe capacity;
- Velocities 0.6 m/s, remaining under velocity of 3.0 m/s;
- Overland flow routes convey storm flows in excess of the 1 in 5 year event;
- Enhanced Water Quality;
- The SWM Strategy focuses on end-of-pipe solutions;
- 10 SWMF proposed west side of Leslie (all off-line); and,
- One (1) retrofit is proposed for water quality (East Holland River Subwatershed Study).

1.5. Data Gaps

The data collected for this project is from a combination of sources including the Town, LSRCA and a variety of other sources. Previous studies, models, files and other data required for this study is based on the information given. It should be noted that within those studies there are some gaps in available information as well as reports that have yet to be completed or reports that are unavailable to the public. Examples of data gaps are:

- Existing storm sewer information;
- Drainage area information outside of settlement areas;
- Uncontrolled outlets; and,
- Existing SWM Pond IDs and reports.

Cole Engineering has done its best to gather all the information available to bring this report together. Further and more detailed studies may need to be completed in order to fill in the missing information.

1.6. Problem and Opportunity Statements

The last four (4) decades of research, monitoring, and scientific studies show how human-related activities, including urban and rural uses, recreation and agriculture, have impaired the health of the Lake Simcoe watershed ecosystem through direct and indirect changes (LSPP, 2009). Further to the objectives identified in the Lake Simcoe Protection Plan, SWM policies call for comprehensive master plans to improve the management of stormwater for both existing and planned development.

Since the implementation of the Lake Simcoe Protection Plan, the Town has retained a consultant (Cole Engineering) to develop a SWMMP to define all anticipated works necessary to maintain, expand and improve the existing storm drainage system (including SWM ponds) while protecting the valued natural resources both within and beyond Town limits. The SWMMP will be prepared in accordance with the Class EA and be available for public review.

This project presents an opportunity to improve the management of stormwater for both existing and planned development which is based on changes in land use as outlined in the Consolidated OP 2031 for the Town (June 2010). An opportunity exists to implement a drainage strategy within the Town to meet the requirements as set out in the Lake Simcoe Protection Plan. While implementing drainage improvements, there will be opportunities to minimize ongoing erosion and sedimentation, phosphorus loadings and changes in water balance which may cause a negative impact on the Lake Simcoe watershed.

1.7. Objectives of the Project

The primary objective of the project is to meet the requirements of the Lake Simcoe Protection Plan (specifically *Policy 4.5 SA*) while considering the intentions of the Town's OP.

The objectives of each plan in detail are described below:

Objectives of the Lake Simcoe Protection Plan

The objectives of the Plan as set out in the Lake Simcoe Protection Act, 2008 are to:

- Protect, improve or restore the elements that contribute to the ecological health of the Lake Simcoe watershed, including, water quality, hydrology, key natural heritage features and their functions, and key hydrologic features and their functions;
- Restore a self-sustaining coldwater fish community in Lake Simcoe;
- Reduce loadings of phosphorus and other nutrients of concern to Lake Simcoe and its tributaries;
- Reduce the discharge of pollutants to Lake Simcoe and its tributaries;
- Respond to adverse effects related to invasive species and, where possible, to prevent invasive species from entering the Lake Simcoe watershed;
- Improve the Lake Simcoe watershed's capacity to adapt to climate change;
- Provide for ongoing scientific research and monitoring related to the ecological health of the Lake Simcoe watershed;
- Improve conditions for environmentally sustainable recreation activities related to Lake Simcoe and to promote those activities;

- Promote environmentally sustainable land and water uses, activities and development practices;
- Build on the protections for the Lake Simcoe watershed that are provided by provincial plans that apply in all or part of the Lake Simcoe watershed, including the Oak Ridges Moraine Conservation Plan and the Greenbelt Plan, and provincial legislation, including the Clean Water Act, 2006, the Conservation Authorities Act, the Ontario Water Resources Act, and the Planning Act; and,
- Pursue any other objectives set out in the Lake Simcoe Protection Plan.

Objectives of Policy 4.5-SA of the Lake Simcoe Protection Plan

Within five (5) years of the date the Plan comes into effect, municipalities, in collaboration with LSRCA, will prepare and implement comprehensive SWMMP's for each settlement area in the Lake Simcoe watershed. The SWMMP's will be prepared in accordance with the Class EA guidelines and will include:

- A characterization of existing environmental conditions on a subwatershed basis, consistent with any relevant subwatershed evaluations, if available;
- An evaluation of the cumulative environmental impact of stormwater from existing and planned *development*;
- A determination of the effectiveness of existing SWM works at reducing the negative impacts of stormwater on the environment, including consideration of the potential impacts of climate change on the effectiveness of the works;
- An examination of any stormwater retrofit opportunities that have already been identified by the municipality or the LSRCA for areas where stormwater is uncontrolled or inadequately controlled;
- The identification of additional SWM retrofit opportunities or improvements to existing SWM works that could improve the level of treatment within a particular *settlement area*;
- A description of existing or planned programs for regular maintenance of SWM works;
- An identification of the recommended approaches for SWM in each *settlement area;* and,
- An implementation plan for the recommended approaches.

Objectives of the Town's Official Plan

The policies of the Official Plan (OP) as it pertains to SWM are to promote and implement effective SWM that will help to reduce erosion; avoid downstream flash flooding; reduce nutrient, siltation and sediment loading; sustain fish habitat; and help to improve the quality of Lake Simcoe and its tributaries. Primary SWM objectives include:

- Ensuring that SWM systems are designed and constructed in accordance with sound environmental and engineering best practices;
- Pursuing and implementing sound SWM practices that will ensure adequate protection from flooding and erosion, maintain and/or improve water quality and enhance the environmental, aesthetic and recreational potential of watercourses; and,
- Reducing phosphorus loading to Lake Simcoe and its tributaries.

From review of the objectives as set out in each plan, the Town's SWMMP objectives are to:

- Investigate opportunities to prevent flooding within the Town;
- Identify existing erosion concerns and recommend erosion control measures;
- Investigate opportunities to maintain and/or improve water quality;
- Investigate opportunities to reduce phosphorus loadings to Lake Simcoe; and,
- Investigate opportunities to mitigate changes in water balance.

It is noted that a key objective of the Master Plan is to comply with the LSRCA Guidance document on 'Comprehensive SWMMP Guidelines' completed in April 2011. This Master Plan and the requirements herein are subject to the guidelines and criteria as outlined in this document.

1.8. Purpose of the Project File

This Project File documents the planning and design process followed and conclusions reached for the Town's SWMMP EA Study. In accordance with the Municipal Class EA planning and design process, the problems and opportunities associated with this study were investigated and documented. Subsequently, a number of alternative solutions were identified and evaluated. This information was presented to stakeholders at a Public Information Centre (PIC) on March 3, 2011. The Project File documents the EA process followed and is structured for ease of public review. In addition to the alternative evaluation, a detailed assessment of existing conditions was developed to meet the requirements of the Lake Simcoe Protection Plan (LSPP). The project file is intended to meet (where appropriate) the objectives as set out in the LSPP, the Town OP and the Municipal Class EA document.

2.0 Planning Context and the EA Planning Process

2.1. Municipal Class EA

The Municipal Class EA (2007) planning and design process was followed for this project as it allows the Town to meet the requirements of the Ontario Environmental Assessment Act (OEAA) for municipal infrastructure without having to either undertake an Individual Environmental Assessment or request a specific exemption for the project. The Class EA is a planning process approved under the OEAA for a class or group of undertakings including municipal infrastructure. Municipal projects included in the Class EA may be implemented without further approval under the OEAA, provided that the approved Class EA planning and design process (**Figure 2-1**) is followed.

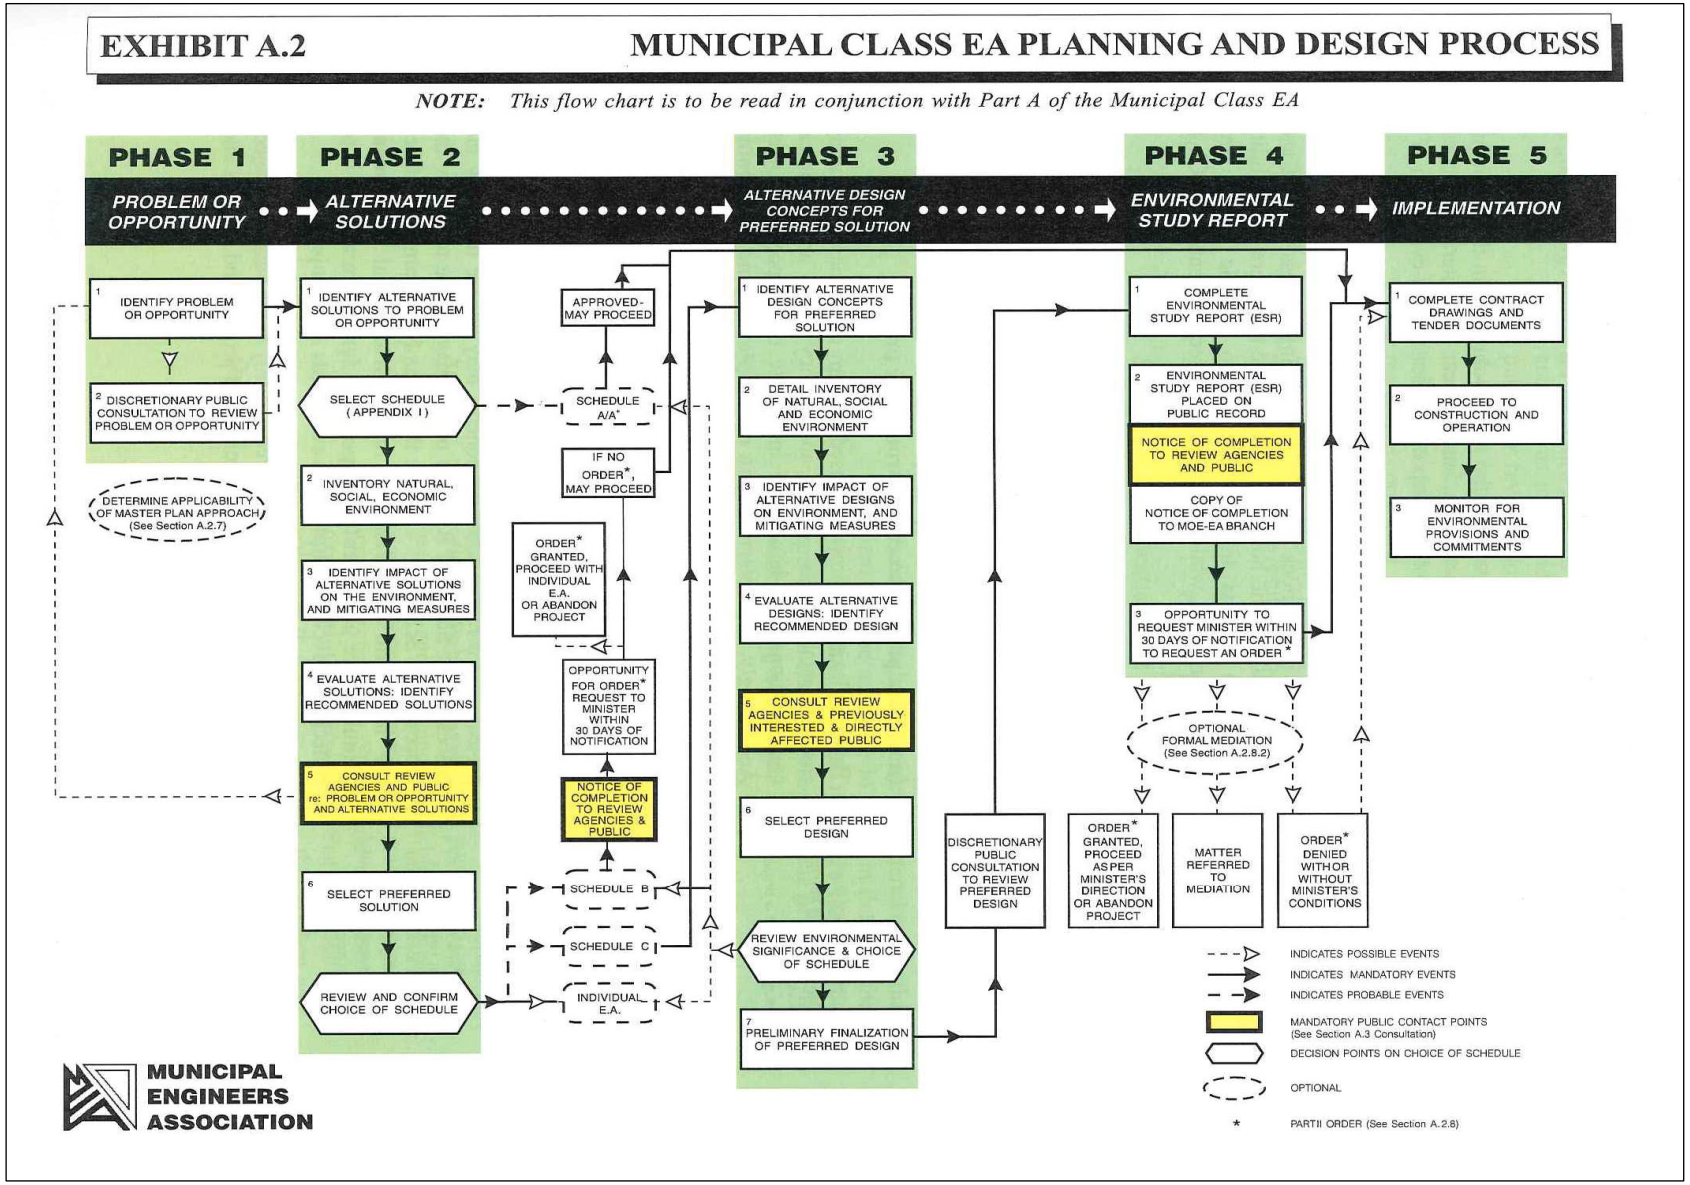

Figure 2-1 – Municipal Class EA Process

2.1.1. Four (4) Project Schedules

Since projects undertaken by municipalities vary in their environmental effects, the Class EA classifies these projects into four (4) schedules according to their environmental significance:

1. **Schedule 'A'**: Projects are limited in scale, have minimal adverse effects and include the majority of municipal maintenance and operational activities. These projects are approved and may proceed directly to Phase Five for implementation without following the other phases.
2. **Schedule 'A+'**: Projects are limited in scale and have minimal adverse effects. These projects are approved and may proceed directly to Phase Five for implementation without following the other phases. However, the public is to be advised prior to project implementation though there is no ability for the public to request a Part II Order.
3. **Schedule 'B'**: Projects have the potential for some adverse environmental effects. The municipality is required to undertake a screening process (Phases One and Two) involving mandatory contact with directly affected public and relevant review agencies to ensure that they are aware of the project and that their concerns are addressed. Schedule 'B' projects require that a Project File report be prepared and submitted for review by the public and review agencies. If there are no outstanding concerns, then the municipality may proceed to Phase Five for implementation.
4. **Schedule 'C'**: Projects have the potential for significant environmental effects and must proceed under the full planning and documentation procedures specified in the Class EA Document (Phases One to Four). Schedule 'C' projects require that an Environmental Study Report be prepared and submitted for review by the public and review agencies. If there are no outstanding concerns, then the municipality may proceed to Phase Five for implementation.

2.1.2. Master Plan Classification

As the Master Plan process does not fall into a specific schedule, they are specified as "long range plans which integrate infrastructure requirements for existing and future land use with environmental assessment planning principles. These plans examine an infrastructure system(s) or group of related projects in order to outline a framework for planning for subsequent projects and/or developments."

Section A.2.7 of the Municipal Class EA document states:

"At a minimum, Master Plans address Phase 1 and 2 of the Municipal Class EA process".

Since the Town's SWMMP Class EA is a high level document relating to the future planning of SWM guidelines and principles, it is classified as a Master Plan project.

2.1.3. Master Plan EA Process

The following activities were carried out for this Study.

Phase One: Identify the Problem / Opportunity

This phase involves identifying the problem / opportunity to be addressed through the study and describing it in sufficient detail to lead to a clear problem / opportunity statement.

Phase Two: Identify and Evaluate Alternative Solutions to the Problem / Opportunity

This phase involves six (6) steps:

1. Identify reasonable alternative solutions to the problem / opportunity (**Section 8.0**);
2. Prepare a general inventory of the existing natural, social and economic environments in which the project is to occur (**Section 3.0**);
3. Identify the net positive and negative effects of each alternative solution, including mitigating measures (**Section 4.0**);
4. Evaluate the alternative solutions (**Section 9.4**);
5. Consult with review agencies and the public to solicit comment and input (**Section 11**); and,
6. Select or confirm the preferred solution(s).

It is noted that the evaluation and selection of a preferred solution is developed on a settlement area basis and is subject to individual site specific analysis during later phases of the EA process. All preferred solutions are to be confirmed at the detailed design stage.

2.2. Public Consultation

In order to fulfill the requirements for a Municipal Class EA, a Public Information Center (PIC) was held on March 3, 2011 at the East Gwillimbury Town Center in Sharon. **Section 11** describes the public consultation process in detail.

3.0 Existing Conditions

3.1. General

This chapter will summarize existing environmental conditions within the Town. It should be noted that for the purpose of this study, existing environmental conditions were based on a review of existing information and documentation specifically the Town consolidated OP 2031. The existing information reviewed is outlined in **Section 1.4** of this report. Further information on the characterization of existing environmental conditions can be found in the Town consolidated OP 2031.

3.2. Natural Environment

3.2.1. Natural Heritage

Natural Heritage features within the Town are identified as wetlands, seepage areas and springs, fish habitat, permanent and intermittent streams, lakes and significant woodlands, all of which need to be protected for the long term. Many of these areas are identified within the Oak Ridges Moraine and Greenbelt areas within the Town (**Figure 3-1**). Protected countryside, which includes the Oak Ridges Moraine and the Greenbelt, represents approximately 75% of the Town. In the OP, the Town supports permanent protection of the Natural Heritage System, key features of the Oak Ridges Morraine and Greenbelt, and the supplementary environmental corridors (**Figure 3-2**).

3.2.2. Natural Hazards

Natural hazards within the Town consist of erosion prone areas and areas within the floodplain. These areas present a natural threat to human safety and the environment. If stormwater is left uncontrolled the risk may increase. The floodplain areas were obtained from the LSRCA. Flooding risks generally occur around watercourses. The Town has numerous wetland areas. These wetlands are largely concentrated in the Holland Marsh area, part of the East Holland subwatershed. Wetlands are often subject to more than one hazard such as flooding, erosion and subsidence which make them poor sites for development. Many of these wetlands are deemed Provincially Significant wetlands in which the Provincial Policy Statement states that "Development and site alternation shall not be permitted on significant wetlands." Significant wetlands, existing flood and erosion hazards are outlined in **Figure 3-2**.

STORMWATER MANAGEMENT MASTER PLAN

NATURAL HAZARDS AND NATURAL HERITAGE AREAS

FIGURE 3-2 **DATE: JAN 2012**

3.2.3. Groundwater Vulnerability

Groundwater vulnerability is also stated as aquifer vulnerability and refers to the shallow groundwater aquifer's susceptibility to contamination from both human and natural sources. The vulnerability of groundwater to contamination depends on soil types, water table elevation, contaminant concentration and the confined / unconfined nature of the aquifer. These areas need to be protected in order to reduce contamination and protect the groundwater. Measures to infiltrate stormwater that are in these areas require detailed studies to ensure that they are not impacting the Town's groundwater. Groundwater vulnerability sites within the Town are illustrated above in **Figure 3-2**.

3.2.4. Groundwater Recharge / Discharge

Discharge potential occurs in areas where the static water table intersects the ground surface. Groundwater discharge areas are often in low topographic areas and can be observed above in **Figure 3-2**. Discharge rates vary throughout the year due to seasonal and longer term changes in recharge and groundwater potentials. Groundwater is replenished as precipitation or snowmelt infiltrates into the ground surface. Significant recharge areas can be described as areas that can effectively move water from the surface through the unsaturated soil to replenish available groundwater resources. Once again infiltration measures in recharge areas require analysis to ensure minimal impact to groundwater. These areas within the Town are also indicated above in **Figure 3-2**.

3.2.5. Well Head and Intake Protection Zones

Wellhead Protection Areas are zones established by the Region of York that are in the vicinity of domestic water supply wells. They are in place to protect groundwater quality from degradations and to ensure sources of water are not compromised in the future as a result of land use decisions. These areas are displayed by *time-of-travel zones* which represent the travel time for groundwater to reach the municipal well.

Wellhead protection areas are based on time travel zones as follows:

- 100 metre pathogen zones around each wellhead; and,
- Time of travel zones of 0 to 2 years, 2 to 5 years, 5 to 10 years and 10 to 25 years.

As per the Town's OP: "the storage or use of pathogen threats by new land uses, including the siting and development of SWM ponds and rapid infiltration basins or columns, except for storage of manure or personal family use, is prohibited within the 100 metre pathogen zone around each municipal well and may be restricted within the 100 metres to two (2) year time of travel zone". The wellhead and intake protection zones within the Town are located below in **Figure 3-3**.

3.2.6. Watercourses / Waterbodies

Significant watercourses within the Town include Holland River, Sharon Creek, Harrison's Creek, Vivian Creek, Mount Albert Creek, Maskinonge River, and Black River (**Figure 3-1**). Cook's Bay is situated NW to the Town, which connects to Lake Simcoe. In addition, other significant waterbodies include Soldier's Bay, Roger's Reservoir and Franklin Pond.

3.2.7. Significant Valleylands

Valleylands are considered to be the "backbone" of a watershed as it supports many important ecological functions such as channelling water and wildlife, and providing a connection between natural heritage features. Valleylands are natural depressions often associated with a river or a stream. In the town of East Gwillimbury, all four (4) subwatersheds contain valleylands. The largest valleyland is within the Black River subwatshed just north of the Oak Ridges Moraine associated with the main branch of the Black River (**Figure 3-2**). Within Secondary Plan Areas the Town identifies valleylands as follows;

- Width of 25m;
- Length of 50m;
- Slope of 15%; and,
- Height of 5 m.

Areas that meet these criteria within the settlement areas are not to be developed or have any type of site alteration. Field investigations are recommended to determine location and appropriate top-of-bank boundary.

3.2.8. Big Woods Policy Areas and Regionally Significant Forests

Regionally Significant forests within the Town consist of Brown Hill Regional Forest as well as Bendor & Graves Regional Forest. The Town has laid out policies to maintain a large percentage of woodland cover and plans for future replacement efforts. The Town has identified where there is a high percentage of woodland cover (**Figure 3-2**). In order to maintain these areas the Town has created the Big Woods Policy to ensure no net loss of woodland cover in these areas. The goal as set out in the OP is to promote and establish programs in increase forest cover of the Town to 30%.

3.2.9. Storm Water Quality and Quantity

To ensure the health and sustainability of the subwatersheds in both the Town and downstream areas, SWM practices are put in place.

The Town's OP outlines the future objectives in regards to SWM and is as follows:

- Ensure that SWM systems are designed and constructed in accordance with sound environmental and engineering best practices;
- Pursue and implement sound SWM practices that will ensure adequate protection from flooding and erosion, maintain and/or improve water quality and enhance the environmental, aesthetic and recreational potential of watercourses; and,

- Reduce phosphorus loading to Lake Simcoe and its tributaries.

Currently, there are no specific SWM standards set in place for the Town. As a part of this study, the development of policies and guidelines for management of the Town's storm drainage system based on current SWM Best Management Practices (BMPs) and development policies and guidelines to apply to future development has been established and further discussed in **Section 12.1.4**.

3.3. Socio-Economic Environment

3.3.1. Agricultural Lands

More than 25% of the Town is farmland and is important to the livelihood of many residents. Agriculture use is mostly for row crops as well as specialty crops grown in the marshes of Holland Landing. Lands designated for agriculture use by the Town are outlined below in **Figure 3-4**.

3.3.2. Land Use

The Town encompasses a mix of land uses including fully serviced urban areas, partially-serviced suburban areas, rural hamlets, estate residential subdivisions and rural agricultural land. The urban areas of East Gwillimbury consist of Green Lane Corridor, Holland Landing, Mount Albert, Queensville and Sharon. A detailed discussion of existing and future land use is provided in **Section 4.2**.

3.4. Municipal Infrastructure

3.4.1. Inventory of Stormwater Management Facilities (SWMF)

The existing SWMF in the Town were inventoried and surveyed by Cole Engineering as a part of this study. Existing SWMF that were accessible and approved by the Town were surveyed and characterized. The most common types of SWMFs in the Town include wet ponds, dry ponds and artificial wetlands. **Section 7.0** further describes the survey process and the database inventory (SWMSoft) utilized. The existing pond inventory is illustrated below in **Figure 3-5**.

3.4.2. Transportation Network

Expansion of Highway 404 is underway and the link between Highways 400 and 404 has been proposed. The extension would improve the capacity of the transportation network in northern York and Simcoe County to meet the forecasted increase in commuter and recreational travel needs. The alignment for the proposed link is conceptual in order to recognize a future route approved by the Provincial accordance with the Environmental Assessment Act and related Controlled Access Highway designation (**Figure 3-1**).

3.4.3. Municipal and Private Services

Throughout the communities of Queensville and Sharon municipal water is available as well as in Bales Drive Industrial Park, located southeast of Sharon. For Mount Albert, municipal water is not currently available for parts of Princess and Albert Streets. Municipal water is not currently available for the areas east of the Holland River and north of Doane Road in Holland Landing.

There are future plans for municipal sewers for the communities of Queensville and Sharon. There are no sewer services currently available for the Bales Drive Industrial Park, located southeast of Sharon. Municipal sewers are installed north of Mount Albert Road, excluding Samuel Harper Court, Haig Crescent and parts of Princess and Albert Streets in the community of Mount Albert. In Holland Landing, municipal sewers are currently located east of Holland River and south of Doane Road. Currently, no municipal sewers are available east of the Holland River and north of Doane Road. In the future, plans are being made for municipal sewers to be installed west of Holland River and south of Holland Landing Road**.**

3.4.4. Utility Corridors

A high voltage transmission line runs through the Town and is illustrated in **Figure 3-1**. Any future high voltage transmission lines should be relocated on the basis of a comprehensive study and in consultation with the Town. Utility infrastructure should be located to minimize any adverse social, land use, visual, environmental or safety impacts. Encouragement should be made to locate the new transmission lines along existing utility corridors or right-of-way (i.e. roads and railways) in order to minimize the fragmentation of properties. Where it is feasible, utility infrastructure should be buried within road allowances.

3.4.5. Summary of Environmental Conditions

The existing environmental conditions as described in **Section 3.0** provide a general characterization of the existing conditions which are consistent with the available subwatershed studies (i.e. East Holland River, West Holland River, Maskinonge River and Black River). Reference should be made to the LSRCA subwatershed studies for detailed information and evaluations on a subwatershed basis. In addition, reference should be made to the Town Consolidated Official Plan 2031 which provides further existing information on a planning perspective.

4.0 Evaluation of the Cumulative Environmental Impact of Stormwater

4.1. General

As set out in Policy 4.5 SA b. of the LSPP, an evaluation of the environmental impact of stormwater from existing and planned development is required based on the changes in land use from the future conditions of the Town's OP 2031.

4.2. Land Use Changes

4.2.1. Existing Land Use

The Town is primarily rural, with a large percentage of the Town's land area used of agricultural purposes. Existing settlement areas include Sharon, Holland Landing, Queensville, Mount Albert and Green Lane West. Existing land uses within the Town can generally be classified into a number of categories, including agriculture, open space, environmental, low-medium residential, institutional, commercial and employment. The existing land use within the Town is illustrated in **Figure 3-4**. The existing land use in each drainage area is summarized in **Appendix A.**

4.2.2. Future Land Use

As outlined in the Town's new Consolidated Official Plan (June 2010), the Town will transition from a rural community of communities to a connected urban area, surrounded by a protected countryside. The Protected Countryside includes the Oak Ridges Moraine and Greenbelt Plan Area, which represent approximately 75% of the Town's land area. While this area will be protected from development, the Town's Central Growth Area will grow into a balanced urban area with a mix of residential, institutional, commercial and employment uses. The future land uses in the Town are illustrated below in **Figure 4-1**. The future land use in each drainage area is summarized in **Appendix B**.

Due to the changes in land use, a comparison of the impacts of stormwater from in relation to peak flows, phosphorus, water budget and erosion will be assessed in the following sections.

4.3. Peak Flow Modelling

4.3.1. General

As part of Policy 4.5 SA of the LSPP, an assessment of stormwater peak flows from existing and future conditions is required to evaluate the environmental impact of the future development in the Town. The hydrologic models and reports received from LSRCA in February 2011 entitled *Hydrologic and Hydraulic Modeling For the West Holland River, East Holland River and Maskinonge River Watersheds* (CCL, 2005) and *Black River Hydraulic Model Update* (LSRCA, 2005) were reviewed and updated to include the revised land use in the Town.

It is noted that only the Future Condition hydrologic models were updated to evaluate the impacts of stormwater as part of this study. The Existing Condition model representative of land use from the end of year 2004 (CCL, 2005 and LSRCA, 2005) was unchanged.

4.3.2. Objectives

The objectives of the hydrologic model update are summarized as follows:

- Assess the changes in peak flows at each subcatchment from existing to future conditions;
- Verify if the future condition lumped approach (CCL, 2005) is required to be updated with the changes in land use within the Town;
- Apply an over control scenario if the future conditions lumped approach (CCL, 2005) does not meet post-to-pre criteria; and,
- Confirm the stormwater criteria and assumptions as outlined in the Hydrologic and Hydraulic Modeling For the West Holland River, East Holland River and Maskinonge River Watersheds (CCL, 2005) and Black River Hydraulic Model Update (LSRCA, 2005) are maintained with the future conditions update.

4.3.3. Model Background

The hydrologic model received from LSRCA which was reviewed and updated was modelled using Visual OTTHYMO Version.2.3. This modelling software allows users to model the storm effects and define the hydrologic input parameters of a given site area.

The main modelling inputs used in the update are described below:

- STANDHYD Command:
  - An area input command mainly used for impervious areas; and,
  - Impervious area input parameters may be assigned to this command.
- NASHYD Command:
  - An area input command mainly used for pervious areas; and,
  - Pervious area input parameters may be assigned to this command.
- ADDHYD Command:
  - An input command used to add two (2) areas together.

- ROUTE RESERVOIR Command:
  - A command used to represent a SWMF or control device; and,
  - The user may input a rating curve to represent a storage-discharge relationship of a SWMF.

It is noted that other existing modelling input commands (i.e. ROUTE CHANNEL and READHYD) were deemed acceptable and were not updated as part of this study.

4.3.4. Hydrologic Model Setup

To update the hydrologic model, an initial review was undertaken to determine the initial set up of the model. The received hydrologic model was developed using a number of approaches. The existing and future condition both incorporate the lumped approach described below:

1. Lumped Approach

All ponds within a subcatchment area are lumped (i.e. all ponds in a single catchment area were lumped into one single pond located at the outlet of the catchment). Under this approach, the discharge and active storage relationship for the lumped pond is determined through the sum of all ponds within a basin based on the return period (CCL, 2005).

Subcatchments are initially divided into two areas: the area that drains into the lumped ponds and the area that does not. The areas draining to the lumped ponds are attributed a numerical suffix of "1" after the subcatchment area ID and the areas not draining to the lumped ponds are given a numerical suffix of "2".

It should be noted that the *Hydrologic and Hydraulic Modeling For the West Holland River, East Holland River and Maskinonge River Watersheds* (CCL, 2005) states that: "the future development within any given subwatershed may include the *approved future development* (future development with approved servicing and SWM plans containing approved future SWMFs) and the *additional future development* (the future development without servicing / SWM plans available). Therefore, the lumped pond within a specific subcatchment under the future landuse condition should include the lumped pond under the existing landuse condition, the storage-discharge relations of the approved future SWMFs, and the to-be-designed SWMFs' storage-discharge relations for the additional future development". The report also states that all SWMFs for additional future development are assumed to be off-line. For more information, reference should be made to the approved *Hydrologic and Hydraulic Modelling For the West Holland River, East Holland River and Maskinonge River Watersheds* Report (CCL, 2005).

To populate each lumped pond (ROUTE RESERVOIR Command), flows and storage values are required to generate the rating curve input parameter. The flow and storage values (i.e. storage-discharge relationship) are developed using average unit flows and unit active storage requirements as described below:

1. a) Post-to-Pre Approach

The "post-to-pre" peak flow control criterion is required for the design of SWMFs for additional future development under the 1:2 to 1:100 year design storms (CCL, 2005). In this Study, the return period control peak flows (rating curve input parameters) were estimated through the average unit flow relationship as per **Table 4-1** below.

Table 4-1 – Average Unit Flow Requirements for SWMFs

Average Unit Flow (m3/s/ha)						
25 mm Storm	1:2 Year Storm	1:5 Year Storm	1:10 Year Storm	1:25 Year Storm	1:50 Year Storm	1:100 Year Storm
0.0034	0.0194	0.0361	0.0500	0.0669	0.0840	0.0978

As per Table C9-A in the Hydrologic and Hydraulic Modeling For the West Holland River, East Holland River and Maskinonge River Watersheds (CCL 2005).

The average storage required for the design of SWMFs for additional future development were estimated in this Study based on the linear regression analysis conducted in the Hydrologic Study (CCL, 2005). The generalized unit active storage requirements were based on the weighted imperviousness, storm return period and control drainage area as per **Table 4-2** below (CCL, 2005).

Table 4-2 – Generalized Unit Active Storage Requirements for SWMFs

Unit Storage (m^3/ha)							
Linear Regression Analysis Paramters	25 mm Storm	1:2 Year Storm	1:5 Year Storm	1:10 Year Storm	1:25 Year Storm	1:50 Year Storm	1:100 Year Storm
C1=Slope	1.867	2.422	2.136	2.106	1.915	1.553	1.201
C2=Intercept	38.173	32.362	86.332	123.051	174.221	227.826	280.180

As per Table C9-B in the Hydrologic and Hydraulic Modeling For the West Holland River, East Holland River and Maskinonge River Watersheds (CCL 2005).

Note: Unit Storage (m^3/ha) = **C1*IMP+C2 = Slope*IMP+Intercept**

It is noted that the "post-to-pre" approach utilized in the original model was adopted in this Study to update the hydrologic model to future conditions.

1. b) Over-Control Approach

In the event the post-to-pre approach does not meet pre-development flow rates, the over-control approach will be applied to the stage-storage-discharge relationships at each future conditions subcatchment. In this approach, revised flows and storage values will be applied *to replace* the average unit flows and unit active storage populated from the post-to-pre approach as discussed above. The resulting peak flows (now below pre-development levels due to the revised stage-storage-discharge relationships) for each storm event will determine the over-control unit-flow rates required for each applicable drainage area. Subsequently, based on the total proposed development area within the drainage area, an over-control unit-flow rate will be generated.

An example of the approach is provided in **Table 4-3** for subcatchment area 9210. It is noted the "over-control" approach is *not* applied to drainage areas already meeting pre-development levels with the application of the "post-to-pre" approach.

Table 4-3 – Over-Control Approach Application to Stage-Storage-Discharge Curve Example (9210)

Event	Post-to-Pre Approach		Over-Control Approach	
	DISCH (m^3/s)	STORAGE (ha·m)	DISCH (m^3/s)	STORAGE (ha·m)
	0.0000	0.0000	0.0000	0.0000
25mm	0.2400	0.5431	0.2000	2.0000
2-year	1.3500	0.5855	1.9000	7.0000
5-year	2.5000	0.9171	2.0000	7.5000
10-year	3.4700	1.1672	2.3000	8.0000
25-year	4.6400	1.4936	3.5000	10.0000
50-year	5.8200	1.8113	4.5000	13.0000
100-year	6.7800	2.1218	5.5000	14.0000

For the above example, with a proposed development area of 176.4 ha, the unit-flow-rate during the 100-year condition is approximately 0.025 $m^3/s/ha$ or 25 L/s/ha. The resulting peak flows and unit flow rates for all storm events are summarized in **Table 4-4** below.

Table 4-4 – Over-Control Approach Application Unit-Flow Rate Example (9210)

CONDITION (DEVELOPED AREA = 176.4ha)	PEAK FLOW (m^3/s)					
	STORM EVENT					
	2-YEAR	5-YEAR	10-YEAR	25-YEAR	50-YEAR	100-YEAR
Pre-Development	1.289	2.078	2.659	3.436	4.041	4.665
Post-Development (Uncontrolled)	16.874	23.724	28.316	34.230	38.702	43.242
Post-to-Pre Approach	8.021	9.711	11.387	13.600	15.259	16.942
Over-Control Approach	1.066	1.778	2.313	3.322	3.875	4.443
Unit-Flow Rate ($m^3/s/ha$)	0.006	0.010	0.013	0.019	0.022	0.025

It should be noted the purpose of the over-control approach is to reduce peak flow rates to below pre-development levels *should* the post-to-pre approach not meet the required quantity control criteria. The over-control approach and supplementary unit-flow-rates are further discussed in **Section 4.3.7**.

4.3.5. Methodology

The existing hydrologic model consists of analyzing the peak flows from individual subcatchments within each subwatershed (East Holland River, West Holland River, Maskinonge River and Black River). As growth within the Town is limited to the existing settlement area boundaries (i.e. Queensville, Sharon, Holland Landing, Green Lane and Mount Albert), adjacent subcatchment areas that drain into or from the settlement areas are analyzed.

The hydrologic modelling update will be conducted through the following steps:

- Identify existing subcatchment areas intersecting each settlement area (i.e. Queensville and Holland Landing); and,

- Divide subcatchment areas into i) Area within settlement area; and ii) External area outside of settlement area (**Figure 4-2**) below.

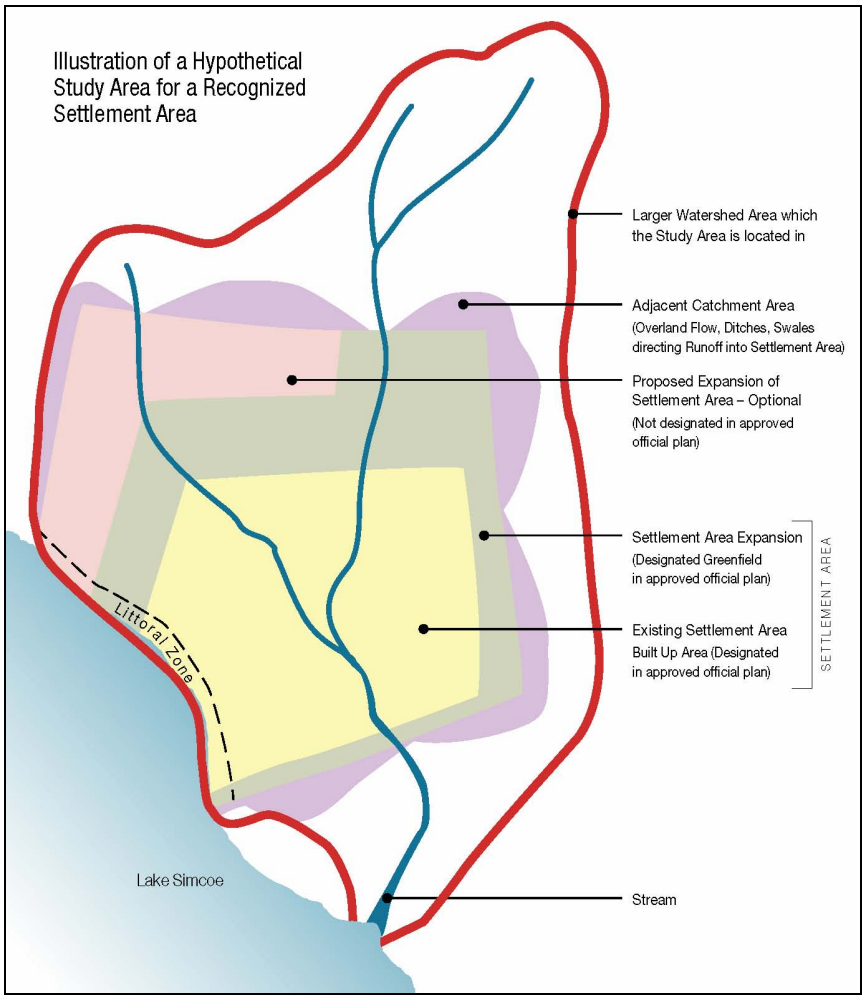

Figure 4-2 – Illustration of Adjacent Catchment Area to Settlement Area (Comprehensive SWM Master Plan Guidelines – April 2011)

- Revise hydrologic input parameters for all applicable drainage areas associated with the changes in land use from the Town's Consolidated OP 2031;
- If the imperviousness of a drainage area > 20%, a STANDHYD command will be implemented, otherwise a NASHYD command will be utilized;
- The existing command type of the external area will be maintained and the area adjusted for the external subcatchment areas; and,
- Compare the revised future peak flows to existing conditions and analyze results.

Due to the number of revisions to the hydrologic models, a numbering system is proposed for subcatchment areas added to the model. For example, if the subcatchment area 244 is located within the Queensville settlement area, the ID will end with a "9" and renumbered as 2449. The modelling numbering system is outlined in **Table 4-5**.

Table 4-5 – VO2 Modelling Numbering System

East Gwillimbury Settlement Area	Numerical Suffix
Queensville	9
Holland Landing	7
Sharon	3
Green Lane	4
Mount Albert	6

It should be noted that the numerical suffixes utilized in the hydrologic modelling and summarized above in **Table 4-5**, are arbitrary in nature and were chosen to not conflict with the existing numerical suffixes used in the Hydrologic and Hydraulic Modeling for the West Holland River, East Holland River and Maskinonge River Watersheds Report (CCL 2005).

To evaluate the effects on peak flows from future development, a number of additional assumptions were made for the purpose of the hydrologic analysis:

- All areas of development within the settlement areas of the Town will be controlled using the "post-to-pre" approach and drain into its own pond (storage-discharge inputs determined from unit flow and unit storage calculations);
- The lumped ponds and storage-discharge inputs remain the same as well as methodologies for calculating hydrologic input parameters;
- If the subcatchment area within the settlement area is <u>less</u> than the area to the lumped pond, the settlement area will be <u>subtracted</u> out and an additional STANDHYD or NASHYD command will be input into the model (**Figure 4-3**) below;

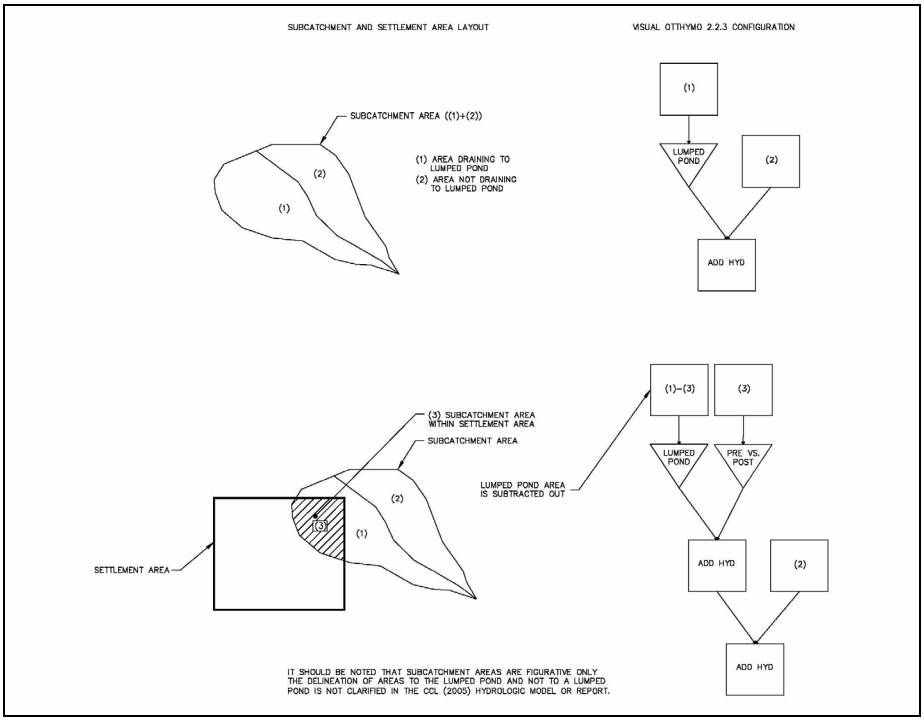

Figure 4-3 – Illustration of Settlement Area Layout and VO2 Configuration I

- If the subcatchment area within the settlement area is greater than the area to the lumped pond, the area to the lumped pond will be replaced (i.e. revised area, hydrologic parameters and numerical suffix). The difference in areas will be subtracted from the area not draining to the lumped pond (**Figure 4-4**) below; and,

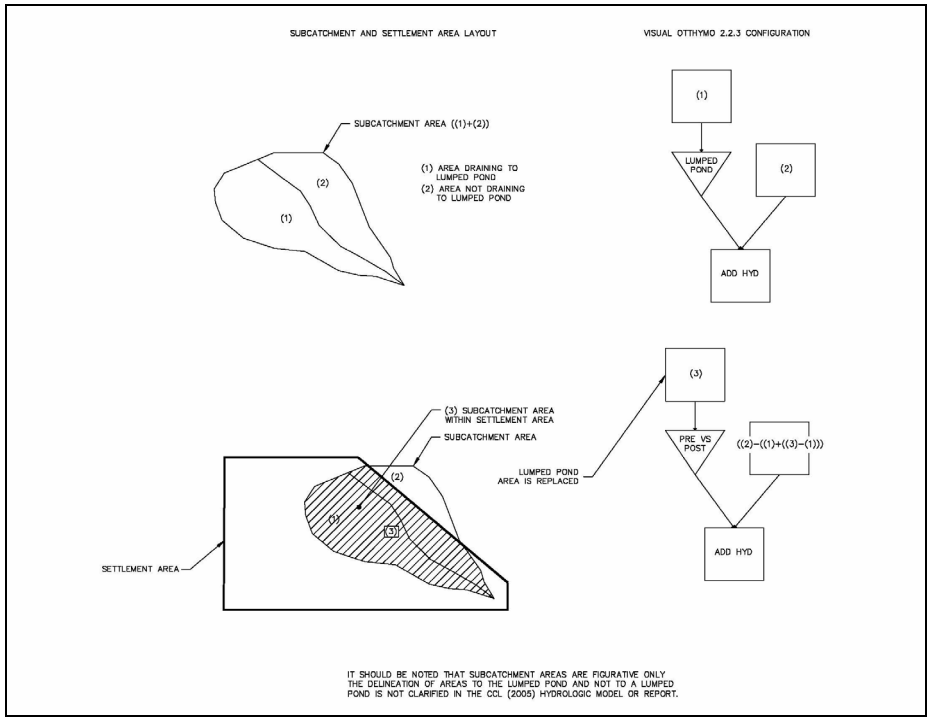

Figure 4-4 – Illustration of Settlement Area Layout and VO2 Configuration II

- All subcatchment areas within the settlement area will drain into its own "post-to-pre" ROUTE RESERVOIR command.

It should be noted that the Black Creek hydrologic model provided by the LSRCA does not include SWM controls (i.e. the lumped approach) and only the necessary pond inputs for the "post-to-pre" approach were input in the future conditions model.

4.3.6. Existing Conditions

The hydrologic model provided by LSRCA included the 12-hour SCS Type II storms for the Holland River and Maskinonge River subwatersheds and the 24-hour SCS Type II storms for the Black River subwatershed. The total rainfall for the subwatersheds during the 2-year to 100-year storm events are summarized below in **Table 4-6**, **Table 4-7**, and **Table 4-8**.

Table 4-6 – Total Rainfall in the Holland River Watershed

Event	12-Hour Holland River Design Storm Total Rainfall (mm)
2-year	42.00
5-year	54.40
10-year	62.70
25-year	73.10
50-year	80.80
100-year	88.50

Table 4-7 – Total Rainfall in the Black River Subwatershed

Event	24-Hour Black River Design Storm Total Rainfall (mm)
2-year	46.38
5-year	66.29
10-year	79.54
25-year	96.10
50-year	108.54
100-year	120.71

Table 4-8 – Total Rainfall in the Maskinonge River Subwatershed

Event	12-Hour Maskinonge River Design Storm Total Rainfall (mm)
2-year	42.00
5-year	54.40
10-year	62.70
25-year	73.10
50-year	80.80
100-year	88.50

An initial review of the existing conditions hydrologic model was conducted and no changes to the input parameters or storm files were made with the updates as a part of this study. The existing condition drainage area plan based on the Hydrologic and Hydraulic Modeling for the West Holland River, East Holland River and Maskinonge River Watersheds Report (CCL, 2005) and Black River Hydraulic Model Update (LSRCA, 2005) is below as **Figure 4-5**. The existing condition hydrologic input parameters sorted by subwatershed are provided in **Table 4-9**.

Total Flow in Subcatchment Area 210 (9210)	East Holland River	1.289	2.078	4.665
Total Flow in Subcatchment Area 214 (9214)	East Holland River	3.693	6.812	20.817
Total Flow in Subcatchment Area 224 (9224)	East Holland River	4.872	6.985	16.438
Total Flow in Subcatchment Area 222 (8164)	East Holland River	5.052	7.127	13.404
Total Flow in Subcatchment Area 208 (8148)	East Holland River	16.017	23.444	54.869
Total Flow in Subcatchment Area 212 (8152)	East Holland River	7.249	10.779	27.704
Total Flow in Subcatchment Area 342 (9342)	West Holland River	1.208	2.057	5.230
Total Flow in Subcatchment Area 422 (9422)	West Holland River	1.144	1.954	4.992
Total Flow in Subcatchment Area 416 (9416)	West Holland River	1.251	2.108	5.193
Total Flow in Subcatchment Area 418 (9423)	West Holland River	0.600	1.014	2.512
Total Flow in Subcatchment Area 414 (8254)	West Holland River	2.277	3.718	11.915
Total Flow in Subcatchment Area 1 (8501)	Maskinonge River	4.905	8.001	19.073
Total Flow in Subcatchment Area 3 (515)	Black River	3.641	6.991	19.085
Total Flow in Subcatchment Area 4 (516)	Black River	2.718	5.388	15.685
Total Flow in Subcatchment Area 6 (518)	Black River	2.663	4.942	12.668
Total Flow in Subcatchment Area 7 (524)	Black River	2.719	5.050	12.958

Note: It is noted that peak flows are not directly additive due to varied time to peak.

4.3.7. Future Conditions

Future Conditions Drainage Characteristics

As stated in **Section 4.2**, the existing and future land uses within the Town are classified into a number of categories and mainly include agriculture, open water / wetlands, forest, open space, medium density residential, low density residential, estate lands, institutional, and commercial. To remain consistent with the original hydrologic model, the average imperviousness and directly connected imperviousness associated with each land use class were adopted from the Hydrologic and Hydraulic Modeling for the West Holland River, East Holland River and Maskinonge River Watersheds Report (CCL, 2005). The average imperviousness values are summarized below in **Table 4-11**.

Table 4-11 – Land Use Classes and Imperviousness

Land Use Class	Avg. Imperviousness	Directly Connected Imperviousness
High Density Residential	55%	25%
Medium Density Residential	45%	15%
Low Density Residential	30%	10%
Estate Residential	15%	5%
Commercial / Industrial / Institutional	75%	70%
Rural Developments	65%	25%
General Urban Areas	45%	15%
Open Space / Recreational	0%	0%
Pasture / Agricultural / Woodlots / Forest	0%	0%
Wetland / Meadows	0%	0%

Note: As per Table 1. Land Use Classes and their Associated Average (CCL, 2005)

It is noted that for consistency purposes, the average imperviousness values were taken from the Hydrologic and Hydraulic Modeling for the West Holland River, East Holland River and Maskinonge River Watersheds Report (CCL, 2005). The average imperviousness utilized from this study may be lower than representative of today's standards and the Town should investigate more recent imperviousness values from neighbouring municipalities when outlining the stormwater management standards. Detailed investigation of appropriate imperviousness values within the Town was not undertaken as a part of this study.

Similarly for rural areas, the same methodology for CN calculations were utilized for the revisions to the future conditions. The CN values associated with land use covers and hydrologic soil groups are provided in **Table 4-12**.

Table 4-12 – SCS Curve Number (CN II) for Land Use Classes and Hydrologic Soil Groups

Land Use Class	Hydrologic Soil Group			
	A Soils	B Soils	C Soils	D Soils
Forest / Woodlots	30	58	71	77
Agricultural / Crops	62	74	82	86
Pasture / Meadows	38	65	76	81
Wetland / Open Water	50	50	50	50
Lawn / Open Space	49	69	79	84
Impervious Area	98	98	98	98

Note: As per Table 2. SCS Curve Number (CNII) for Different Hydrologic Soil Groups and Landuse Covers (CCL, 2005)

The time to peak input parameter was calculated based on the methodology from the existing hydrological reports as well. An average of the results of five (5) times to peak (Tp) equations was utilized in conjunction with the subcatchment parameters (i.e. slope, length, width etc.). The equations consist of the HYMO two-parameter, HYMO three-parameter, Kirpich, Williams & Hann, and Bransby Williams and are described below (CCL, 2005):

HYMO two-parameter: $t_p = 0.016 * A^{0.31} * S^{-0.5}$

HYMO three-parameter: $t_p = 0.0086 * A^{0.422} * S^{-0.46} * (L/W)^{0.133}$

Kirpich Method: $t_p = 0.67 * 0.0195 * L^{0.77} * S^{-0.385} / 60$

Williams and Hann Method: $t_p = 6.54 * A^{0.39} * (S * 100)^{-0.50} / 60$

Bransby-Williams Method: $t_p = 0.67 * 0.057 * L / (S^{-0.50} * A^{0.10})$

Where:

- t_p is the time to peak (hour);
- *A* is the drainage area (ha);
- *S* is the slope (m/m);
- *L* is the watershed length (m); and,
- *W* is the watershed width (m).

Detailed CN, Total Imperviousness (TIMP), Directly Connected Imperviousness (XIMP), and time to peak calculations are provided in **Appendix D**. The future conditions drainage area plan and associated external areas are illustrated below in **Figure 4-6**.

As summarized in **Table 4-1** and **Table 4-2** in **Section 4.3.4**, the storage-discharge relationships for each ROUTE RESERVOIR input for the future conditions model was calculated based on unit equations. The unit flow and unit storage calculations for each subcatchment area are provided in **Appendix E**.

It is noted that as stated in the Hydrology Report (CCL, 2005), the input parameters Initial Abstraction (Ia) and number of linear reservoirs (N) has remained the same during the future conditions due to the model sensitivity of these parameters in the calibrated model.

FIGURE 4-6 **DATE: JAN 2012**

Future Conditions Flow Summary

To evaluate the impacts of the future land use, a comparison of peak flows was conducted as per Policy 4.5 SA of the LSPP. The future peak flow condition results with no mitigation, with post-to-pre quantity control, and over-control are summarized below in **Table 4-13** to **Table 4-41**. Future conditions detailed model output for the 2 to 100-year storm events are provided in **Appendix F**.

Over-Control

As stated in **Section 4.3.4 1.b)**, several future drainage areas are subject to over control (beyond the "post-to-pre" approach) in order to meet pre-development peak flow rates. Over-control involves revising the controlling stage-storage-discharge relationships by applying additional storage or reducing flows for all storm events. Drainage areas subject to the required stage-storage-discharge relationship revisions are given a unit-flow rate ($m^3/s/ha$) criteria (for future developed area only) as indicated below summary tables **Table 4-13** to **Table 4-41** and given a notation of [1].

Table 4-13– Post-Development Peak Flow for Subcatchment Area 244 (Comparison Point 9244)

[1] Over-control approach utilized. Refer to **Table 4-42** for required unit-flow rate.

It should be noted the total rainfall values used in the above quantity control analysis are taken from the original CCL hydrologic model (2005). Developed runoff volumes and peak flows in this SWMMP are based on this older data and as such should be used for reference only. Actual hydrologic data to be used during detailed design of future SWM pond are to be based on the most recent rainfall data and various storm durations in use at the time each future SWM facility is designed.

Results

Table 4-13 to **Table 4-41** above indicate the results of the hydrologic modelling for the future condition land use within the Town. For comparison purposes, columns were added to indicate the "no mitigation" scenario, "post-to-pre" approach and "over-control" approach results. It is noted that the future return peak flows at many comparison points are higher than the existing return period peak flows with the "post-to-pre" peak flow approach applied. This indicates that the "post-to-pre" peak flow control criterion alone may not be enough to limit the future return period peak flows to / below their existing levels (as seen in areas within the East Holland and West Holland River subwatersheds). As a result, the "over-control" approach was applied to comparison points unable to meet pre-development flow rates as indicated below each corresponding summary table. In addition, it should also be noted smaller storm events may reflect a larger difference in flows from the pre-development level and can be adjusted when controls are implemented during the functional stages of development. **Table 4-42** outlines the required unit-flow rates to be applied in each subcatchment area to reduce post-development peak flows to pre-development levels. Calculations of the unit-flow rates are provided in **Appendix F**.

Table 4-42 – Unit-Flow-Rate Summary

Subwatershed	Settlement Area	Sub. Area	Comp. Pt.	Prop. Dev. Area	Unit-Flow Rates ($m^3/s/ha$)

Black River	Sharon	7	524	270.4	0.009	0.016	0.021	0.028	0.032	0.042

Although the application of unit-flow rates will result in reducing peak flow rates at this level of study within the Town, it is desirable to develop a detailed subwatershed based unit flow control criterion, rather than applying the generalized unit flow equations for the entire watershed (CCL, 2005). It is noted that the hydrologic results are analogous to the results in the Hydrologic and Hydraulic Modeling for the West Holland River, East Holland River and Maskinonge River Watersheds Report (CCL, 2005) for the 'post-to-pre' condition and thus recommendations adopted for peak flow control on a subwatershed level. It is noted the unit-flow rates summarized in **Table 4-42** are only applicable to the implementation of the Town of East Gwillimbury Official Plan 2031 at this level of study and detailed stormwater management is required for each new development as outlined by MOE, LSPP and Town standards. In addition, it should be noted the over-control approach in which the unit-flow rates are to be applied, should to be further refined on a subwatershed basis through a detailed unit flow study.

Summary

As indicated above in **Table 4-13** to **Table 4-41**, at some comparison points, the future return period peak flows are relatively close to the existing peak flows (i.e. ±5.0%), and it indicates that the "post-to-pre" peak flow criteria applied to the design of the future SWM facilities does help to control the flood peak flows. As a result, it is recommended that a "post-to-pre" approach be continued to be imposed or enhanced for new developments *and* a unit-storage / unit-flow criteria be applied *until* a detailed unit flow / unit storage criteria is investigated and implemented, specifically within the Black River and Maskinonge River where impacts to peak flows are not as severe. The implementation of unit storage / unit flow criteria can potentially reduce flows within the watershed, reduce erosion downstream and decrease flood potential. It is recommended that a detailed unit flow study is to be investigated (specifically within the Holland River) and implemented in the future.

It should be noted that future SWM facilities within the Town are required to undergo detailed design and control stormwater to guidelines as outlined by the province, MOE and LSRCA. The effects of the future land use on peak flows should be analyzed at a detailed level where the implementation of future SWM facilities in the Town will control the increase in peak flows to each representative subwatershed. In addition, the most current rainfall data and storm durations should be utilized for each future SWM facility design. Further information on recommended SWM practices and SWM criteria is detailed in **Section 12.1.4**.

It should also be noted that a detailed assessment of the hydraulic study was not conducted as a part of this Master Plan. In addition, detailed storm sewer analysis was not conducted. To ensure that future development will not have a negative impact on the Town's storm sewer system, it is recommended that a storm sewer analysis (i.e. flow capacity, infiltration / inflow) be conducted in the future.

4.4. Phosphorus Loading

4.4.1. General

As per the Lake Simcoe Protection Plan's "Phosphorus Reduction Strategy" and detailed in Policy 4.5 SA of the Plan, an assessment of phosphorus loading from existing and planned development is required for all settlement areas within the Town boundary. The Phosphorus Reduction Strategy states that "in order to achieve the ambitious reductions in phosphorus loadings proposed in the Plan, there is a need to reduce loadings from all sources that contribute to excess phosphorus throughout the Lake Simcoe watershed" (LSRCA, 2009). The proposed reduction will be achieved through innovative solutions which will be implemented from the preferred alternative discussed herein. This assessment will evaluate the existing and future phosphorus loadings within the Town's settlement areas and recommend potential mitigation measures to be included in future development work.

4.4.2. Background

Information

Phosphorus is a key water quality concern in Lake Simcoe. While some phosphorus is required to support a healthy aquatic ecosystem, too much of this nutrient leads to excessive growth of plants. Generally, the more phosphorus present in the system, the number of plants and size of the plants will increase. As this biomass dies, decomposing organisms use up available oxygen. Low levels of dissolved oxygen at the bottom of the lake, especially during summer months, are harmful to fish populations and other aquatic organisms. Although reductions in phosphorus have led to improved oxygen conditions in the lake, the improvements are not yet sufficient for the fish to fully sustain themselves naturally. It is therefore an imperative goal for phosphorus loadings to Lake Simcoe to be reduced alongside development for the near future.

Documentation

The following phosphorus loading assessment is based on the detailed study results published by the LSRCA entitled:

- Report on the Phosphorus Loads to Lake Simcoe – LSRCA, 2004-2007, (September 2010).

4.4.3. Methodology

The objectives of the phosphorus loading assessment are summarized as follows:

- Utilize the base case and growth scenario unit area phosphorus loadings from the *Report on the Phosphorus Loads to Lake Simcoe – LSRCA, 2004-2007, (September 2010)* to generate existing and future phosphorus loading rates for each subwatershed;
- Apply the unit area phosphorus loading rate for each subwatershed to each applicable settlement area within the Town; and,
- Assess the changes in phosphorus loadings at each settlement area from existing to future conditions.

It is noted that atmospheric phosphorus (a large portion of the total phosphorus loading to Lake Simcoe) was not accounted for in this study. A phosphorus loading sample calculation is provided below:

Phosphorus Loading Sample Calculation

As outlined in **Section 4.4.3**, phosphorus loading rates were calculated based on the base case and growth scenario unit area phosphorus loadings from the *Report on the Phosphorus Loads to Lake Simcoe – LSRCA, 2004-2007, (September 2010)* to generate existing and future phosphorus loading rates for each subwatershed. Based on the existing and future land use of each settlement area, loading calculations were developed.

A sample calculation for Mount Albert in the Black River subwatershed for a specific land use is provided below. It should be noted the sample calculation is not intended to be exhaustive and should be read in conjunction with detailed phosphorus loading calculations provided in **Appendix G**.

Mount Albert

- *Subwatershed: Black River; Catchment: 3; Land Use: Agriculture; Soil Type: Type B and Type C*

Pre-Development

Existing Load = 0.129 kg/ha (Agriculture)

- For each soil type (Type B and Type C), the existing load is calculated:

Total Existing Load = (89.7 ha x 0.129 kg/ha) + (59.5 ha x 0.129 kg/ha) = 19.3 kg/year

- Similarly, the total existing load for each land use category is added for Catchment 3:

Total Existing Load = 60.9 kg/year

- The total existing load for each drainage area within the settlement area is added:

Total = **87.4 kg/year**

Post-Development

- Similar to pre-development, the revised loading rates are applied to each land use:

Future Load = 0.727 kg/ha (Low Density Residential)

- For each soil type (Type C and Type B, Bottomland and Type A), the future load is calculated:

Total Future Load = (62.2 ha + 84.8 ha + 4.4 ha + 21.1 ha) x 0.727 kg/ha = 125.3 kg/year

- The total future load for each land use category is added for Catchment 3:

Total Future Load = 166.6 kg/year

- The total future load for each drainage area within the settlement area is added:

Total = **226.9 kg/year**

- Based on the difference in loading rate divided by the total proposed future development area, the unit TP removal rate is determined:

Mount Albert Unit TP Removal Rate (kg/year/ha) = (226.9 kg/year – 87.4 kg/year) / 36.9 ha = **3.78 kg/year/ha**

4.4.4. Phosphorus Loading Assessment

As stated above in **Section 4.4.3**, phosphorus loading rates were generated based on the calibrated loadings in the Estimation of Phosphorus Loadings to Lake Simcoe Report (LSRCA, September 2010). Similar to Appendix E of the Estimation of Phosphorus Loadings to Lake Simcoe Report (LSRCA, September 2010), the land use classification has been system has been condensed to the land use categories in the Town described in the existing and future conditions land use in **Section 3.0**. The revised land use classification system and resulting phosphorus loading rates are summarized below in **Table 4-43**. Detailed phosphorus loading unit rate calculations are provided in **Appendix G**.

Table 4-43 – Land Use Categories and Average Annual Phosphorus Loading Rates

CANWET Land Use Category	Existing / Future Condition Land Use	Existing (Base Scenario) / Future (Growth Scenario) Average Annual Phosphorus Loading Rate (kg/ha)			
		Black River	East Holland River	Maskinonge River	West Holland River
Hay-Pasture	Agriculture	0.129 / 0.131	0.251 / 0.247	0.130 / 0.129	0.165 / 0.166
Cropland					
Quarry					
Turf-Sod					
Tile Drainage					
Forest	Forest	0.001 / 0.001	0.004 / 0.004	0.000 / 0.000	0.003 / 0.003
Wetland	Open Water / Wetland	0.139 / 0.137	0.342 / 0.350	0.672 / 0.6226	0.657 / 0.653
Stream Banks					
Groundwater					
Transition	Open Space	0.341 / 0.374	0.385 / 0.478	0.012 / 0.013	1.215 / 1.357
Septics					
Polder					
Unpaved Road	Rural Development, Estate	0.153 / 0.153	0.041 / 0.041	0.083 / 0.068	0.021 / 0.021
Low Intensity Development					
High Intensity Development	Residential, Low Density Residential, Medium Density Residential, Commercial / Institutional	0.393 / 0.727	0.660 / 0.968	0.339 / 0.753	0.246 / 0.451

It is noted that every land use category in the Estimation of Phosphorus Loadings to Lake Simcoe (LSRCA, September 2010) has been incorporated in the phosphorus loading estimate to provide a balanced phosphorus loading calculation.

4.4.5. Existing Conditions

The primary phosphorus loads are generated from the existing developed settlement areas within the Town: Mount Albert, Sharon, Queensville, Holland Landing and Green Lane West. The existing condition subwatershed phosphorus loading rates summarized below in **Table 4-44** were applied to each settlement area on a drainage area basis. The resulting existing condition total phosphorus loadings based on the base case scenario are also provided in the table below. Detailed existing condition phosphorus loading calculations are provided in **Appendix H**.

Table 4-44 – Existing Phosphorus Loadings

Settlement Area	Total Annual Phosphorus Loading (kg/year)
Mount Albert	87.4
Sharon	198.4
Queensville	198.5
Holland Landing	489.9
Green Lane West	192.4

4.4.6. Future Conditions

Future condition land use categories and areas were applied to the future condition phosphorus loading rates from the growth case scenario in the Estimation of Phosphorus Loadings to Lake Simcoe (LSRCA, September 2010). The resulting future condition total phosphorus loadings are provided below in **Table 4-45**. Detailed future condition phosphorus loading calculations are provided in **Appendix I**.

Table 4-45 – Future Phosphorus Loadings

Settlement Area	Total Annual Phosphorus Loading (kg/year)
Mount Albert	226.9
Sharon	338.0
Queensville	857.2
Holland Landing	865.0
Green Lane Expansion Area	811.9

4.4.7. Phosphorus Loading Assessment Results

A comparison of phosphorus loadings is required to assess the environmental impact of development in terms of phosphorus on Lake Simcoe. The phosphorus loading without mitigation assessment is provided in **Table 4-46**.

Table 4-46 – Phosphorus Loading Comparison

Settlement Area (Area)	Existing Total Annual Phosphorus Loading (kg/year)	Future Total Annual Phosphorus Loading (kg/year)	Difference / (% Difference) (kg/year)	Total Proposed Development Area (ha)	Unit TP Removal Rate Required for Mitigation (kg/year/ha)
Mount Albert (358 ha)	87.4	226.9	+139.5 / (+160%)	36.9	3.78
Sharon (468 ha)	198.4	338.0	+139.6 / (+70%)	211.8	0.66
Queensville (1182 ha)	198.5	857.2	+664.7 / (+335%)	54.9	12.1
Holland Landing (1160 ha)	489.9	865.0	+375.1 / (+77%)	37.7	9.9
Green Lane Expansion Area (871 ha)	192.4	811.9	+619.5 / (+322%)	69	8.9

As indicated above in **Table 4-46**, the largest increase in phosphorus loading is in Queensville and Green Lane West (+335% and +322% respectfully) with an increase overall in phosphorus loadings within the Town. In order to mitigate the impacts of development, unit total phosphorus removal rates, SWM controls and innovative water quality approaches are required to reduce phosphorus loadings. The current Total Phosphorus (TP) removal rates accepted by the Ministry of Environment (MOE) for wet ponds and wetlands are 63% and 77% respectively (MOE Phosphorus Budget Tool, January 2012). It should be noted that The *Estimation of Phosphorus Loadings to Lake Simcoe (LSRCA, September 2010)* Report has sufficient information regarding BMPs and phosphorus reduction strategies which may be implemented in the Town.

Phosphorus Mitigation Recommendations

The results of this assessment indicate development will increase phosphorus loadings within each settlement area. It is recommended to implement unit phosphorus removal rates in an integrated treatment train approach (i.e. lot level, conveyance and end-of-pipe controls) to mitigate the accumulation of phosphorus from proposed development (i.e. bioretention, infiltration trenches, permeable pavement, perforated pipe systems, etc.). Further information on potential mitigation measures (and BMP's) is provided in **Section 8.2**. It is noted that specific mitigation measures to be used to reduce phosphorus accumulation are to be confirmed on a site specific basis at the functional design stages of development.

4.5. Water Budget

As per Section 4.8-SA in the Lake Simcoe Protection Plan, a water budget assessment is required under the Lake Simcoe Protection Plan for the existing and proposed land use in the Town. To characterize the environmental impacts of the future conditions, a water budget consisting of the assessment of rainfall, runoff and evapotranspiration to determine infiltration deficit will be developed.

4.5.1. General

To conduct the water budget, each settlement area is considered separately. The settlement areas of Mount Albert, Queensville, Holland Landing, Sharon, and the Green Lane Employment Expansion Area were analyzed. Existing and future development conditions for each settlement area are compared and a volume deficit is determined. As required by the Lake Simcoe Protection Plan, a development must minimize changes in annual infiltration between pre-development and post-development conditions. The water balance analysis for the Town under existing and future conditions was completed on an average annual basis. The detailed water balance calculations are provided in **Appendix J** and summarized in **Table 4-47** to **Table 4-52**.

4.5.2. Background

A major consequence of urbanization is the increase of imperious areas, which changes the hydrologic characteristics within each settlement area and thus increases the amount of stormwater runoff. The Town is expected to expand rapidly over the next 20 years which will change the land use and decrease the amount of infiltration. Urbanization also decreases the amount of evapotranspiration due to the reduction of pervious area. This can potentially cause flooding, increases in velocity of flow during storms, and an increase in annual flow. A water budget assessment is necessary to analyze the potential impacts of development from existing to future conditions.

4.5.3. Water Budget Assessment

The Town consists of 25 different underlying soil types. These soils are categorized with the following textures: sandy loam, loam, sand, clay loam, silt loam, and muck.

A figure outlining the current soil conditions is illustrated below in **Figure 4-7**. These soils were grouped together based on their hydrologic soil group and four (4) soil groups were created. Soil areas designated as Muck were assigned a soil type that was consistent with the most conservative soil type in that drainage area. Land use was separated into agriculture, open water grouped with provincially significant wetlands, forest, medium density residential, low density residential, and estate, institutional, commercial, and open space. Based on Chapter 3 of the MOE drainage manual, and the land zones as given by the Town, the existing and future water budget parameters were developed and land uses were grouped as follows: Agriculture was considered as moderately rooted crops, forest as mature forest, open space as pasture and shrubs, and the remaining as urban lawns. Open water and wetlands are removed from the water budget calculations as their area is consistent from existing to future development. The impervious areas were calculated by the same methodology as was completed in the Hydrologic and Hydraulic Modeling for the West Holland River, East Holland River and Maskinonge River Watersheds Report (CCL, 2005) for the watershed as prepared by the Lake Simcoe Region Conservation Authority.

The water budget assessment infiltration rates were calculated based on the sample calculations located on *Page 3-5* of *Chapter 3* of the *MOE SWMP Manual (2007)*. A water budget sample calculation for the Mount Albert settlement area is provided below to outline the methodology and process:

Water Budget Sample Calculation

A sample calculation for Mount Albert is provided below utilizing the process outlined on *Page 3-5* of *Chapter 3* of the *MOE SWMP Manual (2007)*. It should be noted the sample calculation is not intended to be exhaustive and should be read in conjunction with detailed water balance calculations provided in **Appendix J**.

Mount Albert

Pre-Development Conditions

- *Land Use: Forest, Soil Type: Type B*
- Based on land use and soil type, Evapotranspiration (ET) values were derived from *Table 3.1* of the *MOE SWMP Manual (2007)*:

ET = 548 mm

- Surplus (mm) is calculated by subtracting the ET (mm) from the total annual precipitation (901.2 mm).

Surplus = Precipitation – ET = 901.2 mm – 548 mm = 353.2 mm

- Infiltration (mm) is calculated by multiplying Surplus (mm) by the cumulative infiltration factors derived from *Table 3.1* of the *MOE SWMP Manual (2007)* based on topography, soils and cover. In this case, topography is flat land (0.3), soils are open sandy loam (0.4) and cover is woodland (0.2).

Infiltration = Surplus * (Cumulative Infiltration Factors) = 353.2 * (0.3+0.4+0.2) = 317.9 mm

- Average annual land use infiltration is calculated by multiplying total area of the land use by infiltration:

Average annual land use infiltration = 1.14 ha * 317.9 mm = 362.4 ha·mm = 3624 m^3

- This method is repeated for each soil type and land use within all the drainage areas within the settlement area (refer to **Appendix J** of the SWMMP).
- The total annual site infiltration volume is the sum of all infiltration values in the settlement area.

Total infiltration (mm) = **804805.5 m^3** / 314.5 ha = 255.9 mm

- A similar approach is conducted for Post-Development – No Mitigation Conditions with larger impervious areas generating a reduced total infiltration (mm).

Total infiltration (mm) = **693192 m^3** / 278 ha = 250 mm

- The annual infiltration rate required by each settlement area (Table 4-52) is the infiltration deficit divided by the total future development area:

Annual infiltration rate (m^3/ha/year) = (804805.5 m^3 – 693192 m^3) / 36.9 ha = **3025 m^3/ha/year**

Mount Albert Settlement Area

The settlement area of Mount Albert expects to undergo some development by 2031 according to the Town's OP. There will be in increase in commercial and industrial areas and a decrease in forest, and open space. The impervious area will increase from 12% to 22%. This increase of impervious area will create an infiltration deficit of 312.12 m^3/ha.

The Mount Albert settlement area contains all four (4) soil types (**Figure 4-8**) below, but consists mainly of Type A and B soils which are classified as well draining according to Table 3.1 of the SWM Planning and Design Manual (MOE SWM Planning and Design Manual (2003)). The water budget for Mount Albert is provided below in **Table 4-47**.

Table 4-47 – Mount Albert Water Budget

Infiltration (m^3)	693192	0	693192

Queensville Settlement Area

Under existing conditions, Queensville is mostly agriculture with a small amount of land designated for residential. Queensville is anticipated to grow into a mixed use urban area, with a mix of residential, employment and commercial uses. The imperviousness will increase from 3% to 21%. Post-development rates must meet pre-development rates. The deficit is 315.26 m^3/ha. Soil types in Queensville are of all four (4) types, and about half of the settlement area made of well draining soils (**Figure 4-9**) below. The water budget for Queensville is provided in **Table 4-47**.

Holland Landing Settlement Area

This settlement area is partially developed under existing conditions. To accommodate future growth, Holland landing will acquire an employment and commercial area, as well a growth in residential lands. There is a large section of land that is designated as Provincially Significant Wetland or open water that surrounds the East Holland River (**Figure 4-10**) below. This area does not change. Imperviousness will increase 18% mostly due to the high percent impervious that commercial and employment areas have. The infiltration rate that the post-development is required to meet will ask for land to infiltration 273.46 m^3/ha. The water budget for Holland Landing is provided in **Table 4-49**.

Sharon Settlement Area

The Sharon Settlement Area is approximately half developed under existing conditions, but will grow to mostly residential area. The infiltration rate is 305.16 m^3/ha, due to the increase in imperviousness (19% to 27%). The area made of well draining soils that are ideal for infiltration measures (**Figure 4-11**) below. The water budget for Sharon is provided in **Table 4-50**.

Green Lane Expansion Areas

This area consists of the two (2) expansion areas along Green lane, including a proposed Community and Employment Area. Under existing conditions these lands are almost all agriculture with the exception of some residential and forested area. The future conditions will double the impervious area and require an infiltration rate of 456.21 m^3/ha. Again this settlement area is comprised wholly of well draining soils ideal for infiltration measures (**Figure 4-12** and **Figure 4-13**) below. The water budget for the Green Lane Expansion Area is provided below in **Table 4-51**.

Rural Areas

The rural part of East Gwillimbury is considered as unchanged and no development being done on this land. Rural areas consist of all soil types with the main landuse zoned for agricultural use. All landuses will remain the same; hence pre and post infiltration rates are matching.

Results

A summary of the water balance results are provided below in **Table 4-52**.

Table 4-52 – Water Budget Comparison

Settlement Area	Pre-Dev Runoff (m^3)	Post-Dev Runoff (m^3)	Increase / % Increase (m^3)	Pre-Dev Infiltration (m^3)	Post-Dev Infiltration (m^3)	Decrease / % Decrease (m^3)
Mount Albert	694362	982748	288386 / +41.5%	804806	693192	111614 / -13.9%
Queensville	1525657	2946591	1420934 / +93.1%	2891837	2519174	372663 / -12.9%
Holland Landing	2946591	3089303	142712 /	2519174	2360389	158785 /

Settlement Area	Pre-Dev Runoff (m^3)	Post-Dev Runoff (m^3)	Increase / % Increase (m^3)	Pre-Dev Infiltration (m^3)	Post-Dev Infiltration (m^3)	Decrease / % Decrease (m^3)
			+4.8%			-6.3%
Sharon	1188063	1525271	337208 / +28.4%	929402	786586	142816 / -15.4%
Green Lane Expansion Areas	1540894	2338484	797590 / +51.8%	1851071	1453618	397453 / -21.5%

A summary of the annual infiltration rates required by each settlement area (proposed development area only) are provided below in **Table 4-53**.

Table 4-53 – Annual Infiltration Rates Required by Each Settlement Area

Settlement Area	Future Development Area (ha)	Required Infiltration Rate (m^3/ha/year)
Mount Albert	36.9	3025
Queensville	211.8	1760
Holland Landing	54.9	2892
Sharon	37.7	3788
Green Lane Expansion Areas	69	5760

Based on the analysis, a general increase in runoff will occur during the post-development condition with a reduction in infiltration. The largest increase in runoff occurs in Queensville and the greatest reduction in infiltration occurs in the Green Lane Employment Expansion Area. These areas will require the implementation of BMPs in an integrated treatment train approach to mitigate the loss of infiltration from the proposed changes in land use. Alternative BMP practices are further discussed in **Section 8.2**. It should be noted that specific mitigation measures are to be confirmed on a site specific basis at the functional design stage.

4.6. Erosion Analysis

4.6.1. General

Stormwater runoff can cause severe erosion concerns if uncontrolled runoff continues to drain into the watercourse with a lack of stabilization measures. Erosion can occur on stream banks from flow in the watercourse or runoff. This can change the characteristics of the stream by widening and decreasing the depth due to sediment accumulation. Sediments may also be carried in runoff from bare agricultural lands or construction sites.

The LSRCA and the Town are committed to decreasing the amount of sediment that is being carried into Lake Simcoe as well as its tributaries.

As per Policy 4.5 SA of the LSPP, an erosion analysis of existing and future conditions is required. This section of the SWMMP will detail the existing erosion study and relevant erosion analysis recommendations to be applied to future developments and studies.

4.6.2. Background

Erosion is of concern within in the Town due to the large percentage of agriculture land, and numerous watercourses. Agricultural lands are particularly vulnerable when they are bare (e.g. after tilling, or in the spring) and can contribute large amounts of sediment from runoff. In rural areas, farmers may remove vegetation along watercourses in order to maximize arable land and in doing so contribute to stream bank instability and erosion. In urban areas, impervious surfaces can increase the volume and velocity of stormwater runoff, leading to an increase in streambank erosion, and sediment deposition.

4.6.3. Existing Conditions

An erosion site survey was completed by the LSRCA in 2008. The LSRCA conducted a BMP Inventory, spanning 12 sections of the 18 subwatersheds within the Lake Simcoe basin.

The subwatershed studies of the East Holland River, West Holland River, Maskinonge River and Black River assess this study and provide details of the BMP opportunities where applicable. The purpose of the BMP inventory was to identify opportunities for the reduction of nutrients or improvements to fish habitat within the Lake Simcoe basin (LSRCA, 2010). As part of the study, existing erosion sites within the watercourses were identified. The erosion sites within the Town are depicted above in **Figure 3-2**.

4.6.4. Future Conditions

In order to mitigate existing erosion points and prevent future erosion sites the following recommendations have been made.

The mitigation of stream bank erosion will need to be completed on a site by site basis following a more detailed analysis. Proponents may suggest the most appropriate manner to solve the erosion such as the use of rip-rap or amourstone however; the LSRCA encourages the use of natural channel designs and “soft solutions”. This includes improving riparian vegetation that may have been removed or damaged. The vegetation helps to stabilize the banks decreasing erosion and phosphorus loading. Increasing the ‘buffer’ zone to at least 15 m around watercourses will help increase bank stability, filter excess nutrients from surface runoff, reduce soil erosion and improve water quality.

The implementation of traditional BMP measures will help control the volume of stormwater as well as mitigating sediment erosion concerns. Measures such as wet ponds, grassed swales, and wetlands enhance sediment removal by increasing detention times. These measures can also decrease urban runoff which is known to change the flow patterns in rivers increasing erosion. In addition, SWM pond retrofits may reduce erosion by eliminating uncontrolled outfalls and upgrading existing SWMF to higher protection levels.

Fluvial Assessments

Future developments within the Town will be required to conduct a fluvial geomorphological and erosion assessment of the receiving watercourse by a qualified fluvial geomorphologist. The objectives of the assessment will be to identify areas of ongoing channel adjustment and to develop appropriate mitigation measures to limit future impacts. As future developments will contribute runoff to a watercourse, an assessment is required in order to ensure that changes upstream as a result of development will not adversely impact the creeks.

It should be noted that the detail of the fluvial assessment (if required) should be confirmed with the LSRCA along with any other applicable approval agencies.

A fluvial assessment of a receiving watercourse typically consists of:

- An analysis of existing geomorphic conditions:
  - Aerial photography (i.e. changes in channel movement over time);
  - Field work results (i.e. site photos, measurement of channel dimension parameters); and,
  - Cross sections and profiles of the channel.
- Rapid Field Assessments:
  - RSAT Evaluations;
  - Stability Index (SI) Interpretation; and,
  - Analysis of Qualitative Habitat Evaluation Index.
- Erosion Thresholds:
  - The point at which sustained flows will tend to entrain and transport sediment, specifically the D_{50} of the substrate material; and,
  - Development of critical shear stresses and critical flow (on reach basis).
- Flow Duration Analysis Recommendations.

The fluvial assessment should result in future modelling recommendations (i.e. event-based modelling vs. continuous modelling) and establish the critical flow for the receiving reach which is necessary to conduct the supplementary erosion exceedance analysis for the development. The erosion exceedance analysis will set the extended detention criteria for the site (i.e. 24hr, 48hr or 72hr extended detention) which will retain stormwater on site mitigating adverse erosion impacts downstream.

Smaller development sites that prove to have minimal impact to the watershed may only be required to maintain “good housekeeping” practices. These include monitoring mud tracked from the construction site, controlling silt and debris being washed into storm sewers and watercourses, and controlling wind blown dust. The Lake Simcoe Protection Plan is proposing policies to minimize the amount of dust erosion generated from construction sites that may impact future developments. Sites with greater impact to the watershed require greater sediment and erosion control similar to traditional BMP measures as well as maintaining “good housekeeping” practices. Erosion and sediment controls should be monitored during and after construction.

It should be noted that detailed erosion analysis of creeks within the Town will not take place as part of this study. The Town will investigate the opportunity for individual erosion assessments where development will take place (e.g. Sharon West development) or if another major opportunity for stabilization arises. The next two (2) phases of the EA Process will feature detailed erosion assessments on an individual development basis.

5.0 Effectiveness of Existing SWM Works

5.1. Existing SWM Assessment

5.1.1. General

As part of Policy 4.5 SA of the LSPP, a determination of the effectiveness of existing SWM works is required to assess the existing reduction of negative impacts of stormwater on the environment. This requirement involves the verification of the existing pond control structure works and a supplementary sensitivity analysis to examine the existing SWM effectiveness within the Town. See **Section 4.0** for the effectiveness of using a lumped pond approach for the different Community Areas in maintaining downstream peak flows. It is noted that **Section 6.0** through **Section 7.0** of this report detail the examination and verification of existing SWM works (i.e. quality of existing SWMF). The following section will only detail the sensitivity analysis requirement performed on the existing SWMF within the Town.

5.1.2. Background

A review of existing information was conducted and the hydrologic and SWM reports received from the Town that were reviewed for this assessment are listed below:

- Pond 23: Technical Design Brief SWMFs, York Region Industrial Subdivision 19T-94016, Cumming Cockburn Limited (CCL) (July 2004);
- Pond 17: SWM Analysis for Amberglen Estates Phase III File 19T-89091, A.M. Candaras Associates Inc. (December 1994);
- Pond 21: SWM Plan – Manors of Forest Ridge, Town of East Gwillimbury, URS Cole, Sherman (June 2001); and,
- Pond 18: SWM for Riverstone Estates Draft Plan 19T-89117, Greenland International Consulting Inc. (July 2002).

The pond locations used in the sensitivity analysis are illustrated on **Figure 3-5**. It is noted that to perform the sensitivity analysis, only select existing SWMF were reviewed and implemented. The sensitivity analysis methodology is further explained in **Section 5.1.4** of this report.

5.1.3. Objectives

To assess the effects of climate change on the existing SWM works, a hydrologic model will be established to reproduce the SWMF designs of select SWMF within the Town. A sensitivity analysis will then be applied to determine the effects on the representative peak flows and storage volumes of the existing SWMF.

The objectives of the verification and sensitivity analysis of the existing ponds are summarized as follows:

- Verify the hydrologic input parameters (i.e. Drainage Area, CN, TIMP, XIMP, and rating curve) from select existing SWMF within the Town where applicable;
- Develop a sensitivity analysis by adjusting CN values and the 100-year storm event rainfalls and intensities by factors of 25% to simulate the effects of climate change; and,
- Comment on the effects on quantity performance (i.e. peak flows and storage volumes) of the existing SWM works within the Town including a number of assumptions regarding climate change.

5.1.4. Methodology

To conduct the sensitivity analysis, a balanced assessment of existing SWMF characteristics must be developed. The sensitivity analysis will be established through the following seven (7) steps:

- Identify four (4) existing SWMF within Town boundaries which are designed to receive runoff from:
  - A large urbanized drainage area (**Pond 23**);
  - A small urbanized drainage area (**Pond 17**);
  - A large rural drainage area (**Pond 21**); and,
  - A small rural drainage area (**Pond 18**).
  - Utilize existing information from existing SWM reports and drainage area plans to establish the corresponding hydrologic input parameters for each SWMF;
  - Replicate the hydrologic model with Visual OTTHYMO v2.3. and run under the 100-year storm event;
  - Adjust the duration of the 100-year storm event (from 12hr to 6hr and 24hr) to simulate the effects of climate change on short and long duration storm events;
  - Adjust the 100-year storm event rainfall intensity by factors of 25% by modifying the storm parameter (RFACT) to simulate the effects of climate change on low and high intensity storm events;
  - Adjust the CN input parameter (from $CN_{AMC\ II}$ (average) to $CN_{AMC\ I}$ (dry) and $CN_{AMC\ III}$ (wet) to simulate the effects of climate change on the antecedent moisture conditions of the soils; and,
  - Comment on the resulting effectiveness of the existing SWMF (i.e. changes in peak flow and storage volumes) in response to climate change.

5.1.5. Existing SWM Input Parameters

The existing SWM input parameters for the four (4) selected SWM ponds are summarized below in **Table 5-1**.

Table 5-1 – Sensitivity Analysis SWM Input Parameters

Pond ID	Subwatershed	Subcatchment Type (ID)	Area (ha)	CN	TIMP (%)	XIMP (%)	Tp (hr)	SLPI (%)	LGI (m)
23	Black River	STANDHYD (3010)	26.95	76.0	79	79	-	1.5	423.87

	0.139	0.580
	0.192	0.615
	0.254	0.651

It is noted that the Pond IDs correspond to the pond survey IDs described in **Section 7.0** (as implemented by SWMSoft) and a figure detailing the pond locations is provided as **Figure 3-5**.

5.2. Hydrologic Modelling Results

The 100-year storm (SCS Type II 12hour) for the Black River and East Holland River subwatersheds were run to evaluate the existing outflow and storage volume used in each SWMF. This scenario of hydrologic modelling is called the 'base model'. The resulting peak flows and storage volumes of the base model are summarized below in **Table 5-6**.

Detailed hydrologic model output is included in **Appendix K**.

Table 5-6 – Post-Development Base Model Peak Flow and Storage Volumes of Existing Ponds

Pond ID	Storm Event	Rainfall	$Q_{OUTFLOW}$	Storage Used
	year	mm	m^3/s	ha·m
23	100	121	1.312	2.3738
17	100	89	0.242	0.1402
21	100	121	0.198	2.1785
18	100	121	0.004	0.2723

5.3. Sensitivity Analysis

In support of the evaluation of the existing SWM works within the Town, a sensitivity analysis was conducted of the modelling. The resulting peak flow hours and storage volumes of the base model were evaluated against a variation in storm event duration, rainfall intensity and CN values. The revised CN values for each SWMF are summarized below in **Table 5-7**.

Table 5-7 – Sensitivity Analysis Variation in CN Value

Pond ID	Subwatershed	Subcatchment Type (ID)	Area (ha)	CN_{AMCII}	CN_{AMCI}	CN_{AMCIII}
23	Black River	STANDHYD (3010)	26.95	76.0	58.0	88.0
		STANDHYD (3020)	5.36	62.0	42.0	79.0
17	East Holland River	STANDHYD (101)	2.60	60.0	40.0	77.0
		STANDHYD (102)	3.75	60.0	40.0	77.0
		NASHYD (103)	2.23	60.0	40.0	77.0
		NASHYD (104)	1.96	60.0	40.0	77.0
21	Black River	STANDHYD (204)	1.46	65.5	46.0	82.0
		STANDHYD (206)	2.65	65.5	46.0	82.0
		STANDHYD (207)	4.86	65.5	46.0	82.0
		STANDHYD (210)	1.64	55.0	35.0	73.0
		NASHYD (203)	1.91	57.3	37.0	74.0
		NASHYD (205)	5.45	58.7	39.0	76.5
		NASHYD (208)	4.31	57.0	37.0	74.0
		NASHYD (209)	3.63	56.3	36.0	76.5
		NASHYD (101)	30.00	54.2	34.0	72.5
18	Black River	STANDHYD (1)	5.22	50.0	30.0	70.0
		NASHYD (2)	3.63	75.0	56.0	88.0
		NASHYD (3)	1.52	80.0	63.0	91.0

The results of the sensitivity analysis for peak outflows and storage volumes of each evaluated SWMF are presented below in **Table 5-8** and **Table 5-9**.

Table 5-8 – Sensitivity Analysis Results (Peak Flow)

Condition / Adjustment	Peak Flow (m^3/s) / Percent Change from Base Model			
	Pond 23 (Large Urban)	Pond 17 (Small Urban)	Pond 21 (Large Rural)	Pond 18 (Small Rural)
Base Model / None	1.312	0.242	0.198	0.004
6hr / 100-year Storm Duration	0.322 / -75.5%	0.129 / -46.7%	0.137 / -30.8%	0.002 / -50.0%
24hr / 100-year Storm Duration	1.008 / -23.2%	0.887 / +266.5%	0.199 / +0.5%	0.005 / +25.0%

	Peak Flow (m^3/s) / Percent Change from Base Model			
-25% / Rainfall Intensity	0.367 / -72.0%	0.090 / -62.8%	0.188 / -5.1%	0.003 / -25.0%
+25% / Rainfall Intensity	3.201 / +144.0%	0.426 / +76.0%	0.210 / +6.1%	0.006 / +50.0%
AMC I Conditions / CN	1.110 / -15.4%	0.078 / -67.8%	0.187 / -5.6%	0.003 / -25.0%
AMC III Conditions / CN	1.465 / +11.7%	0.469 / +93.8%	0.212 / +7.1%	0.006 / +50.0%

Table 5-9 – Sensitivity Analysis Results (Storage Volumes)

Condition / Adjustment	Storage Volume (ha·m) / Percent Change from Base Model			
	Pond 23 (Large Urban)	Pond 17 (Small Urban)	Pond 21 (Large Rural)	Pond 18 (Small Rural)
Base Model / None	2.3738	0.1402	2.1785	0.2723
6hr / 100-year Storm Duration	1.4025 / -40.9%	0.1161 / -17.2%	0.6826 / -68.7%	0.1056 / -61.2%
24hr / 100-year Storm Duration	2.3143 / -2.5%	0.2771 / +97.6%	2.2347 / +2.6%	0.2931 / +7.6%
-25% / Rainfall Intensity	1.9950 / -16.0%	0.1080 / -23.0%	1.2766 / -41.4%	0.1820 / -33.2%
+25% / Rainfall Intensity	2.6535 / +11.8%	0.1793 / +27.9%	3.2137 / +47.5%	0.3716 / +36.5%
Dry AMC I Conditions / CN	2.3421 / -1.3%	0.1055 / -24.8%	1.1871 / -45.5%	0.1996 / -26.7%
Wet AMC III Conditions / CN	2.3975 / +1.0%	0.1883 / +34.3%	3.3906 / +55.6%	0.3694 / +35.7%

It is noted that the variable conditions as summarized above in **Table 5-8** and **Table 5-9** outline the assumptions by which climate change may have an impact on existing SWMF. Detailed climate change assessments were not completed as part of this study.

Results

By inspection and as shown above in **Table 5-8** and **Table 5-9**, the peak outflows are generally sensitive for a shorter duration storm for all drainage areas, where modelling indicates that a 25% change from the Base Model value results in a greater than 25% change in the peak flow, either positive or negative. Similarly, longer storm duration is the most sensitive to the peak flows from a SWMF draining a small urbanized area. The storage volumes generally decrease during short storm events as expected and increase (with the exception of the large urban area) during longer duration storms. To summarize, the existing ponds would operate at normal conditions for short storm events (i.e. peak flows and storage volumes are adequate) and during longer storm events the pond outflows and storage volumes would generally increase.

Alternatively, the peak flows are generally not sensitive to a 25% reduction and increase in rainfall intensity for rural areas. Peak flows from SWMFs draining urban areas however are very sensitive to decreases and increases in rainfall intensity. Pond volumes are generally not sensitive to changes in rainfall intensity for ponds draining urban areas and are sensitive in rural areas. In addition, moisture conditions of the draining soils are generally sensitive to ponds draining smaller drainage areas for both peak outflows and storage volumes. This would suggest that larger ponds would still operate at a normal level during saturated ground conditions as a result of climate change.

The sensitivity analysis provided above in **Table 5-8** and **Table 5-9** indicates that the changes in the conditions of storm events and hydrologic parameters on the existing SWMF in the Town are generally sensitive in terms of peak outflows and storage volumes.

It should be noted that the sensitivity analysis performed is to simulate the assumed hydrologic instability based on climate change. Climate change is variable in nature and cannot be wholly assessed as part of this analysis.

5.4. Climate Change

The LSRCA realizes that the concept of Climate change is still an evolving term but needs to be addressed as it is expected to influence, directly and indirectly all elements of the Lake Simcoe Watershed. Climate change may potentially impact the Town by having an increase in phosphorus loading, increase in sediment and contaminants in flood transportation, reduction in ground water flows, variation in stream flow regimes, and changes in precipitations, lake levels, erosion, and ice cover. The Conservation Authority would like municipalities to investigate comprehensive master plans which will consider the potential impacts of climate change on the effectiveness of SWM works. This is detailed in the above sections. Future risk assessment and adaptation planning may need to be completed once the impacts of climate change have been confirmed.

6.0 Examination of Stormwater Retrofit Opportunities

6.1. General

The Lake Simcoe Basin SWM and Retrofit Opportunities (2007) Report by the LSRCA has identified the need for a complete, consistent, and contemporary data set associated with stormwater runoff in the Lake Simcoe Watershed. This data set includes all urban catchments, outlets, existing SWMFs and locations, and phosphorus loads associated with stormwater runoff. This report also identifies retrofit opportunities including facilities that can be upgraded, or areas that can support a SWMF.

The retrofit opportunities in the Town include:

- Three (3) in Sharon;
- 20 in Holland Landing; and,
- Six (6) in Mount Albert.

A detailed list, including type of retrofit, size of SWMP, phosphorus reduction rate, and an estimated cost is available in the report which is publicly accessible on the LSRCA website (www.lsrca.on.ca). The existing SWM retrofit opportunities within the Town including uncontrolled outlets and areas of a potential SWMF retrofits are illustrated above in **Figure 3-5**.

6.2. Examination of Existing Retrofit Strategy

Alongside the LSRCA, the Town has identified areas and existing facilities that will require a retrofit. Most of these facilities have been identified in the Lake Simcoe Basin SWM and Retrofit Opportunities (2007) and previous reports and studies completed by the LSRCA. The Town and LRSCA have paired to advance projects where funding is available through the Lake Simcoe Clean Up Fund. This is an ongoing effort and the overall goal is to permit all existing facilities within the Town to meet Enhanced requirements.

6.3. Retrofit Strategy Development

Generally, in the absence of a Town retrofit strategy, the development of a new retrofit strategy is required as part of the Policy 4.5 SA of the LSPP. However, as per discussion with LSRCA staff, a new retrofit strategy is not required at this time due to the overall 2007 strategy completed by LSRCA.

The existing areas requiring retrofit should correspond to the areas identified by the LSRCA in the Simcoe Basin SWM and Retrofit Opportunities (2007) Report. The development of the retrofit strategy of existing SWMFs will result from the implementation of SWMSoft SWMF software. Existing SWMFs were surveyed and recommendations based on existing operating conditions are developed as a part of the SWM Maintenance Program detailed in **Section 7.0** of this report. In addition, the SWMSoft Inspection Report and Bathymetric Surveys are included in **Appendix L**.

7.0 SWM Maintenance Program

7.1. Introduction

The Town is responsible for the operations and management of 26 identified SWMFs including both wet and dry ponds. As part of the Great Golden Horseshoe, East Gwillimbury is expected to grow from 23,000 to 86,400 residents by 2031. To effectively manage this population growth, the Town has requested the examination of current SWMFs as part of this Master Plan.

Cole Engineering was retained by the Town to conduct a SWMF Assessment and Maintenance Study to facilitate the on-going management of these SWMFs, and promote effective management techniques. This report presents a summary of findings collected.

7.1.1. Objective

The objective of this section is to:

- Collect field and existing document information of all the Town-owned facilities;
- Conduct a detailed field assessment and evaluate all of SWMFs and their components;
- Estimate available permanent pool volumes in assumed wet ponds;
- Assess the operation and maintenance requirements to keep the facilities in proper operating condition;
- Forecast future maintenance requirements including tasks, resources, schedules and costs; and,

- Implement a database management system to facilitate on-going operations and maintenance.

A good maintenance plan should be proactive, demonstrating due diligence by calling for a comprehensive collection and analysis of data. It should prioritize inspections and maintenance works for repairs and restorations. Performing accurate assessments of individual facilities is necessary to determine the requirements for staff, physical and budget resources required for maintenance. In the long run, proper planning reduces liabilities and costs.

7.2. Background

The Town currently is responsible for the operation and management of 26 assumed SWMFs, and by 2031, the Town will be responsible for a multitude of SWMFs both wet and dry.

Most of the ponds are designed and constructed by developers in accordance with current SWMF design standards and ownership is transferred to the Town once the construction associated with the development area is complete.

7.3. Function and Maintenance of SWMFs

SWMFs have been introduced to mitigate the impacts of urban runoff from existing and new development areas.

Depending on their design, SWMFs can provide:

- Flood protection;
- Water quality treatment;
- Erosion control;
- Base flow augmentation;
- Infiltration;
- Spill management;
- Aesthetics; and,
- Buffer between urbanized areas and/or natural areas.

The following sections describe the basic functions, along with related maintenance activities, that can keep SWMFs operating as intended.

7.3.1. Applicable Legislation, Regulations and Guidance Documents

The following section provides discussion on legislation, regulation and guidance documents which are currently applicable to the construction, operation and maintenance of SWMFs from the federal, provincial, municipal level.

Fisheries Act

The Department of Fisheries and Oceans (DFO) is the implementing agency of the *Federal Fisheries Act*. Section 35 of the Act prohibits the Harmful, Alteration, Disruption and Destruction (HADD) of fish habitat and Section 36 of the Act prohibits the release of substances deleterious to fish habitat. Where a HADD cannot be avoided a Letter of Authorization may be issued by the DFO detailing required mitigation and habitat compensation measures. During the permit issuing process DFO determines whether approval under the *Canadian Environmental Assessment Act* (CEAA) is required for the project. This determination would be based on the decision regarding a HADD.

LSRCA has an agreement with the DFO to identify fish habitat impacts within their watersheds. In addition, the CAs provides co-ordination and assistance to DFO for review and assessment of projects, which may impact fisheries and/or fishery habitat. In general SWMFs are not considered fish habitat, however, natural wetlands, lakes and the creeks connected to SWMFs are. As such, it is the responsibility of the Town to ensure that proposed works which may affect wetlands, lakes and creeks do not have a negative impact on the natural fish habitat.

Canadian Environmental Assessment Act

In most cases, Federal Environmental Assessments are not applicable for work associated with SWMFs, however, one can be triggered if a designated licence, permit, or approval such as an authorization for a HADD under the *Fisheries Act* is required. In general, an environmental assessment is a process to predict the environmental effects of proposed initiatives before they are carried out. They can be fairly straight forward or be subject to a comprehensive study reviewed at the federal level depending on the potential environmental impacts.

Ontario Environmental Assessment Act

Establishment of new SWMFs is subject to the Municipal Class Environmental Assessment Process described by the Municipal Engineers Associations, 2007 in accordance with the *Ontario Environmental Assessment Act*.

The Class EA planning takes into consideration the protection of all aspects of the natural, social and economic environment as well as long-term planning for the mitigation of any adverse effects during both construction and commissioning. The Class EA process also includes consultation with the Public, First Nations, Government Agencies, local interest groups and review bodies to obtain input and feedback and to ultimately attain general acceptance for the preferred alternative.

The design and construction of most SWMFs would follow the Schedule A Class EA process since they would be required as a condition of approval of site plan, or plan of subdivision and would come into effect under the *Planning Act* prior to the construction of the facility. Modifications or retrofits to SWMFs are subject to a Schedule A+ Class EA. Most other new SWMFs would follow the Schedule B Class EA process.

Places to Grow Act and the Greenbelt Act

"*Places to Grow*" is the Ontario Government's initiative to promote sustainable growth and development in the Greater Golden Horseshoe. The plan outlines the framework for infrastructure including water and wastewater infrastructure. It supports the policies identified in the Greenbelt and encourages innovative SWM actions.

Ontario's Greenbelt is an area of permanently protected green space, farmland, forests, wetlands and watersheds. The Greenbelt Plan covers approximately 1.8 million acres of environmentally sensitive and agricultural land in the Golden Horseshoe. SWMFs within the Greenbelt are subject to the requirements of the Greenbelt Plan which are aimed at the protection of key natural features and key hydrologic features.

Lakes and Rivers Improvements Act

The Ministry of Natural Resources (MNR) is the lead agency responsible for the management of fish resources in Ontario. MNR approval is required under the *Lakes and Rivers Improvement Act* for the placement of structures to convey and dissipate flows. Potential changes to the rivers streams or stormwater ponds may be required MNR approval.

Ontario Water Resources Act

As per the Ministry of the Environment (MOE) Certificate of Approval (C of A) issued under Section 53 of the *Ontario Water Resources Act*, owners of SWMFs are responsible for maintaining them in proper working condition.

This means operating as per the original design specifications and includes all components in the original design such as inlet and outlet structures, side slopes, sediment forebay, shading measures, erosion protection lining, manhole covers and the approved volumes.

The C of A clearly outlines the legal requirements where the owner must:

> *"ensure that the works will be operated, maintained, funded, staffed, and equipped in a manner enabling compliance with the terms and conditions…such that the environment is protected and deterioration, loss, injury, or damage to any person or property is prevented"*

With regards to sediment removal, the owner must understand that:

> *"regular removal of sediment from the approved SWM works is required to mitigate the impacts of sediment on the downstream receiving watercourse. It is also required to ensure that adequate storage is maintained in the SWMFs at all times, as required by the design"*

Within a municipal context, developers typically build and own the SWMFs as part of the development block, and they are responsible for maintaining them in proper operating condition. However, the responsibility shifts when the municipality assumes ownership. Prior to transferring ownership to the Town, an as-built survey should be completed to ensure that the facility was built and maintained in accordance with the C of A. A full clean out should also be conducted on the facility to return it to the full permanent pool volume as per the original design requirement, unless the survey indicates a minimal amount of accumulated sediment (Drake & Guo 2008).

The MOE provides the following Guidance Documents to understand the requirements of SWMFs and assist with the application for a C of A:

- MOE. SWM Planning and Design Manual. March 2003; and,
- MOE. Section 53, Ontario Water Resources Act. Sample Application Package for a Sanitary Sewage and Stormwater Collection System & SWMF Certificate of Approval. June 2009.

Ontario Municipal Act

The *Municipal Act* empowers individual municipalities to adopt by-laws, policies and guidelines to suit the goals and needs of each local community. The Town has developed standards for SWMFs as described in Section 4 of the Subdivision Design Manual, dated February 2005. The manual outlines the requirements imposed by the Town for the design and preliminary maintenance needs for new SWMFs.

Conservation Authorities Act

Section 28 enables the Conservation Authority to make Regulations prohibiting, regulating or requiring the permission of the authority for straightening, changing, diverting or interfering in any way with the existing channel of a river, creek, stream or watercourse, or for changing or interfering in any way with a wetland.

The Lake Simcoe Region Conservation Authority (LSRCA) is authorized through O.Reg. 179/06, Regulation of Development, Interference with Wetlands and Alterations to Shorelines and Watercourses.

Through this Regulation, the CA may prohibit work from taking place within valley and stream corridors, wetlands and associated areas of interference. Any work which falls within the regulated areas described as follows is subject to this regulation:

- Straightening, changing, diverting or interfering in any way with the existing channel of a river, creek, stream or watercourse, or for changing or interfering in any way with a wetland;
- Development, if in the opinion of the authority, the control of flooding, erosion, dynamic beaches or pollution or the conservation of land may be affected by the development; and,
- Where Development is defined as:
  - The construction, reconstruction, erection or placing of a building or structure of any kind;
  - Any change to a building or structure that would have the effect of altering the use or potential use of the building or structure, increasing the size of the building or structure or increasing the number of dwelling units in the building or structure;
  - Site grading; and/or,
  - The temporary or permanent placing, dumping or removal of any material, originating on the site or elsewhere.

Endangered Species Act

In general, engineered SWMFs such as wet ponds and dry ponds are not considered fish habitat, however, they may discharge to creeks which provide habitat for endangered species. In such situations, provisions need to be made to protect the habitat and ensure that no impacts occur. Wetlands and lakes, however, can be considered fish habitat and it would be necessary to consider the requirements under this act. If it is suspected that endangered species are within the study area, the MNR should be consulted to determine if specific measures are required.

Environmental Protection Act

Proper management of SWMFs will require periodic maintenance to restore the permanent pool volume. Sediment quality, management and disposal of impacted dredged material should adhere to MOE requirements:

- MOE. Guidance on Sampling and Analytical Methods for Use at Contaminated Sites in Ontario. December 1996;
- O.Reg. 153/04 as amended by O.Reg. 511/09 – *Records of Site Condition*; and,
- O.Reg. 347/90 as amended by O.Reg. 558/00 – General Waste Management.

Oak Ridges Moraine Conservation Plan

Any development that is to occur on lands under the Oak Ridges Moraine Conservation Plan (ORMCP) legislation must be accompanied by a stormwater management plan as set out in section 46 of the Oak Ridges Moraine Conservation Plan. The objectives of a stormwater management plan are to; maintain groundwater quantity and quality; protect aquatic species and their habitat; prevent increases in stream channel erosion; and; prevent any increase in flood risk. The ORMCP would prefer to have an integrated treatment train approach that uses a planned sequence of methods for controlling stormwater and minimising impacts.

Lake Simcoe Protection Plan

Further discussion is provided above in **Section 1.0**.

7.4. Methodology

The following section describes in detail the methodology undertaken to assess each facility's maintenance needs and collected data. During the course of the study, design drawings and reports were scanned into electronic files to allow instant access from the software.

These files were also used to populate the database with all relevant information regarding the SWMFs. All of the field data necessary to complete the study was collected from winter 2010 to present. This data includes facilities, components, inspection results, maintenance recommendations, and bathymetric survey results.

7.4.1. Database Development

The design of the database was completed early in the project. The design involved merging data from the Town with Cole Engineering's SWMF management database, SWMSoft. Most of the data from the Town database consisted of facility information (name, type, function and location) as well as data referring to its functionality (drainage area, slope, and drainage length). It should be noted that the data collected had gaps and require further refinement. Additional tabs consisted of five (5) main groups:

1. Attributes;
2. Inspection;
3. Maintenance;
4. Hydrology; and,
5. Resources.

7.4.2. Attribute Data

The attribute data set contains the physical characteristics of a facility or component, for example, its location or parent component. The relationships between facilities and components (inlet, outlet, and berm) and between a parent component (inlet) and its child component (baffle blocks, headwall, and grate) were stored so that components could be easily found and logically stored in a tree view. This was limited to a degree of two (2) to reduce unnecessary complexity in the system.

7.4.3. Inspection Data

Inspection information was stored after each inspection of the facility. This data includes the inspector, condition of the component, comments by the inspector, date of inspection, condition ranking and photo.

Components assessed include:

- General facility appearance;
- Inlet and outlet structures;
- Low flow channels;
- Emergency overland spillway;
- Vegetation;
- Access road and walkways;
- Perimeter fencing;
- Any unusual situations within the facility such as the presence of erosion, unsafe conditions, nuisance issues, encroachments, poor water quality, etc.;
- Sediment accumulation; and
- Public safety.

The condition ranking system is the basis for the maintenance assessment of the facilities and components. A condition ranking between 1 and 5 was given, where:

1 = Excellent (the component has no deterioration);

2 = Satisfactory (some wear is noticed, but does not affect the functionality of the component);

3 = Attention Required (the component is still functioning but has minor problems that may prevent the component from functioning properly during extreme events – some simple upkeep is required);

4 = Non-Functional (the component is no longer functioning as designed); and,

5 = Safety Hazard (the component presents a safety hazard either because it allows access to restricted areas, e.g. a grate on a pipe is not secure, or the component is structurally unsound e.g. erosion of the access road).

7.4.4. Maintenance Data

Maintenance information was stored when a maintenance task was opened after an inspection. The information stored when a task was opened consists of the maintenance task, the description, type of task (inspection, upkeep, repair, or replacement), a photograph of the component, and any resources needed to complete the task. Resources are discussed in the following section.

When a task is closed, the information on how long the task took, as well as when it was completed can be stored with the original budget and the final cost of completing the tasks. Photographs taken during maintenance can also be stored with the closed maintenance task. By incorporating photographs into every aspect of the system, any user from any department can have a good idea about the current state of a component, as well as how it changes over time.

7.4.5. Resource Data

Internal and external resources available to the Town play an important role in the maintenance of a facility. Resources are used to perform tasks such as repairs and sediment removal. Resources are separated into four (4) groups: Town staff, materials, contractors, and consultants. Each resource is given a cost as well as a unit in terms of time or frequency when tasks are assigned. This allows the number of units of a given resource to be summed in order to render the total cost of the maintenance task. It is important to note that if the rate of a resource is changed, the cost of all open maintenance tasks is also changed in the software. Once the task is closed, the budget for the task is stored together with the actual cost. Thus, a comparison can be made between budgeted and actual maintenance costs, which can be used for future planning.

7.4.6. File Data Collection

Collecting file data is an important step in preparing the maintenance plan. The Town provided numerous scanned reports with information pertaining to the maintenance of the facilities or their components. All reports, drawings, briefs, and files were reviewed and any facility or drainage area information was added to the database. Existing data gaps are further explained in **Section 1.5**. All drawings and all main bodies, and as much of the appendices as possible of each report were scanned. The scanned images are stored such that they are easy to access from the software, thereby facilitating the search for information.

7.4.7. Field Data Collection

All field data was collected via a GPS or total station survey, digital camera, and inspection sheets. If an assumed permanent pool was associated with the facility, then a bathymetric survey was completed with the Cole Engineering-designed bathymetric rod and boat.

Inspections

During an inspection, each component's location was captured with the GPS station. This data was used to place an icon on the Master drawing, giving a complete picture of the facility. Also, at least one photograph of each component was taken so that future inspections can be compared. Photos, besides of each component, included overviews of SWMFs, upstream and downstream embankment faces, inlets to the SWMF and downstream outfalls from the SWMF and any issues associated with the SWMF. These photos allowed for maintenance tasks to be assigned without the need for further visits.

When performing the visual inspection, all field staff used a general inspection form, included in the SWMSoft report. The Pond ID, subcomponent and parent component were entered, along with descriptions of the component and its location. A ranking from 1 to 5 was selected to indicate the condition of the component and a space for any comments related to the ranking was provided for rankings 3 and higher. A default satisfactory description is available in the software when entering inspection results. The SWMSoft Inspection Report is included in **Appendix L**.

Bathymetric Survey

As mentioned above, if a facility has an assumed permanent pool component, a bathymetric survey was completed as well as the component survey. Bathymetric surveys assessed the quantity of sediment accumulated in the pond. Two (2) methods were used to collect the data, with the second method being used only when the equipment was available.

For both methods, the equipment used included a portable boat, several sections of floating rope, tent anchors, spray paint, and two (2) rods, one (1) neutrally buoyant and the other made of metal. In the first method, a measuring tape and total station survey equipment were also required. In the second method, global positioning system (GPS) survey equipment was used instead of a total station.

The first step in the process consisted of examining the site for suitable cross-sections that would provide enough points to develop the model, in locations where there were likely changes in depth. In most cases, cross-sections spaced evenly every 10 – 15 m across the entire pond were completed. Anchor points were sprayed or flagged, numbered, and surveyed along the water's edge where the cross-section meets the water. Upon completion of the staking, a rope was strung across the cross-section to keep the boat in a straight line.

In the first method, the measuring tape was secured to the anchor. The rope was used to keep the boat in a straight line between the cross-section points and the tape measure was used to ensure a point was taken every 5 m (2.5 m if the cross-section was very narrow). The total station survey equipment was used to take an X-Y coordinate position in relation to a benchmark determined on the SWMF. In the second method, GPS survey equipment was used, and UTM coordinates were recorded at every point and sediment and pond bottom depth were measured. These measurements were taken approximately every 5 m.

To measure the sediment depth, the neutrally buoyant bathymetric rod was allowed to slowly sink until it rested on the sediment. Once the reading was taken, the metal rod was threaded through the neutrally buoyant rod and the sediment until it reached the original bottom of the pond. This process continued across the entire pond to complete the bathymetric survey.

The bathymetric survey provided multiple cross-sections across the entire pond. These points were then compiled to create a digital terrain model of the two surfaces. This is explained in the following section and detailed in **Appendix L**.

7.4.8. Permanent Pool Volume Analysis

Cole Engineering began analyzing the permanent pool volume using the coordinates of each pond as well as each point in the cross-sections inputted into the software. The software then generated the Northing, Easting, and an elevation points for the sediment and pond bottom for each measurement. Next, the points were imported into AutoCAD Civil 3D and into Digital Terrain Models that we generated to create an accurate model of each pond. From this model, we calculated the current sediment volume and the remaining permanent pool volume. Generated drawings for each facility show the top of sediment contour lines and several cross-sections of the pond. The volumes of both permanent pool and active storage, if available, are also displayed. Drawings are included in the Bathymetric Surveys provided in **Appendix L**.

Assess Maintenance Requirements

After completing inspections, all components with a condition rating of 3, 4, or 5 were evaluated for their maintenance needs. To create the maintenance task and to allocate the resources needed to complete it, photographs and comments made by the inspector were used. For each task, a related photograph taken during the inspection was selected in order that those performing the maintenance would have a visual of what the task would entail. While adding a due date and reminder date was possible, this was not done since the Town could more appropriately provide future work schedules.

7.5. Results

7.5.1. Inventory

A comprehensive inventory of the Town's SWMFs can be found in the SWMSoft report and a key map is provided in **Figure 6**. This inventory lists the ponds by Pond ID and provides information regarding the facility name, pond type (i.e. wet pond, and dry pond.), facility function, facility type (offline or online), facility status (assumed or unassumed), and whether or not a bathymetric survey was completed.

7.5.2. Inspections

A summary of inspection results for all ponds, listed by Pond ID, is generated by SWMSoft and is included in the SWMSoft report in **Appendix L**. All ponds with at least one (1) component ranking 3, 4 or 5 are highlighted in **Table 7-2** as they require immediate maintenance.

7.5.3. Permanent Pool Volume Analysis

Based on the bathymetric surveys and permanent pool volume analysis, the sediment volume, remaining permanent pool volume, and total pond volumes are displayed in the SWMSoft report along with a recommended sediment removal timeframe. Bathymetric drawings for the ponds that are over 40% full of sediment are provided in the SWMSoft report. The MOE *SWM Planning and Design Manual* (2003) recommends storage volumes based on drainage area and MOE protection level, which determines the efficiency at which the pond removes sediment. Drainage area and protection level information was not available for all ponds in order to calculate the necessary sediment volume to be removed so as a general rule, ponds with >50% sediment accumulation was considered to require immediate sediment removal.

The ponds identified as requiring immediate sediment removal are 01, 08, 10 and 17. Pond 15 is recommended to have sediment removed within the next five years.

Upon review of the design reports available for these ponds, it appears that the amount of sediment accumulation exceeded initial predictions. It is possible that proper erosion control plans were not implemented during construction of the subdivision. In discussion with the Town, it was determined that the ponds had not been dredged prior to assumption by the Town, which may account for some of the excess accumulated sediment. It should be noted that some of the ponds assumed by the Town were designed and built before the MOE guidelines went into effect. Before a sediment plan is attempted, we recommend reviewing the possibility of a retrofit that would update the facility to current standards as the area surrounding the pond will, in any case, need to be disturbed and any necessary equipment will already have to be in place. The SWMSoft Inspection Report and Bathymetric Surveys are included in **Appendix L**.

7.6. Sediment Removal Process

7.6.1. Background Review

Since each SWMF has specific site characteristics, it is important to conduct a thorough Background Review to identify approvals requirements, evaluate alternative approaches and develop an optimal sediment removal program.

Review of Available Information

In order to obtain a good understanding of the scope of the program, certain documents should be reviewed in detail including:

- A comprehensive bathymetric survey which outlines the estimated quantities requiring removal;
- SWM Design Drawing, or Drainage Plans; and
- Other reports on retrofits and maintenance.

Field Investigations

A site visit should be conducted to collect additional information about the existing site conditions. As part of the site visit: sediment sampling, topographic survey, condition survey of the pond structures, SWMFs areas and adjacent properties, possible access routes, tree protection / removal requirements, utilities, temporary storage area of sediments, etc. should be assessed.

Public Consultation / Liaison

Communication with the local community is a key component in the successful execution any major program. It will be important to inform adjacent private property owners of the work to be carried out on the SWM facilities. Information to be provided to the private property owners will include, but not limited, to the following:

- Construction access to the SWM facility;
- Method of sediment removal and dewatering;
- Potential generation of dust during dewatering operations;
- Possible noise level due to sediment removal and dewatering operation;
- Odour impact;
- Duration of sediment removal and dewatering operation; and,
- Timing of sediment removal and dewatering operation.

Any required easement and construction access through private properties will be identified in the early stages of the design and discussed with affected property owners.

Agencies Consultation and Approvals

Permitting and approval requirements for each pond may differ depending on Site conditions (i.e. on-line vs. off-line, within regulated areas, or if significant environmental impacts are anticipated). It will be important to consider what legislation and regulations are applicable. **Table 7-1** below provides a discussion on potential legislation applicable in the management of SWMFs. The key regulatory agencies which may be involved with sediment removal processes are included below in **Table 7-1**.

Table 7-1 – Discussion on Potential Legislation

Agency	Applicable Approvals
Department of Fisheries and Oceans	Wetlands, lakes, and on-line ponds which provide fish habitat would need to be reviewed for federal requirements. If a Harmful, Alteration, Disruption and Destruction (HADD) of fish habitat or a release of substances deleterious to fish habitat is anticipated, the DFO should be consulted. The DFO can also determine whether approval under the Canadian *Environmental Assessment Act* (CEAA) is required for the project.
Ministry of Environment	Sediment removal is considered a regular maintenance activity and would generally require a Schedule A Environmental Assessment unless if environmental impacts are anticipated. Other work may trigger other requirements and should be reviewed on an individual basis. Sediment quality, management and disposal of impacted dredged material should adhere to MOE requirements: MOE. Guidance on Sampling and Analytical Methods for Use at Contaminated

Agency	Applicable Approvals
	Sites in Ontario. December 1996. O.Reg. 153/04 as amended by O.Reg. 511/09 - *Records of Site Condition* O.Reg. 347/90 as amended by O.Reg. 558/00 – General Waste Management
Ministry of Natural Resources	In most cases, MNR involvement is not anticipated for the management of sediments in SWMFs, unless changes to flows in rivers, creeks or discharges from SWMFs are expected. If it is suspected that endangered species are within the project area, the MNR should be consulted to determine if specific measures are required.
Lake Simcoe Region Conservation Authority	Some SWMFs fall within regulated areas which are mapped by the CAs who regulate and may prohibit work from taking place within valley and stream corridors, wetlands and associated areas of interference and the Lake Ontario waterfront.
York Region	Construction access may be required on Regional property. Tree Removal / Protection By-Law may need to be reviewed as part of the development of the sediment removal.

Management of Sediments

During field investigations, sediment samples should be collected to develop a basic understanding of the physical and chemical properties of the sediment materials.

Sampling should be conducted using a protocol and methodology as described in the MOE Guidance on Sampling and Analytical Methods for Use at Contaminated Sites in Ontario Document, dated December 1996.

Analysis to characterize sediment properties should include:

- Grain size analysis;
- Inorganic parameters and nutrients (Moisture content, Total Organic Carbon, TKN, ammonia, nitrate, nitrite, phosphorus);
- Full suite of analysis as per the O.Reg. 347/90 as amended by O.Reg. 558/00; and,
- Full suite of analysis as per the O.Reg. 153/04 as amended by O.Reg. 511/09.

All analysis shall be conducted at a Canadian Association for Laboratory Accreditation (CALA) Accredited Laboratory. Understanding the physical properties can help in evaluating the various sediment removal options.

Comparison of analytical results with criteria defined by O.Reg. 558/00 can determine whether materials are classified as hazardous wastes. If materials are classified as hazardous wastes, then disposal options are limited to hazardous waste receivers. If materials are not hazardous wastes, then various disposal options can be considered.

Comparison of analytical results with the "soil criteria" defined by O.Reg. 511/09 (Soil, Ground Water and Sediment Standards for Use Under Part XV.1 of the Environmental Protection Act, July 2009) can help in establishing whether sediments meet acceptable environmental criteria for different types of land-uses. According to the amended regulations, non-hazardous soils meeting certain land-use criteria can be transported as fill material to another property with equal or less stringent criteria.

Sediment sampling conducted prior to removal can provide a general understanding of conditions which can be expected during removal, however, additional sampling of materials as they are excavated will be required if they are to be transported off-site to ensure they are disposed of in accordance with all applicable statutory and receiver requirements. O.Reg. 511/09 requires at least one (1) soil sample shall be analyzed for each 160 cubic metres of soil for the first 5,000 cubic metres and at least one sample for each additional 300 cubic metres of soil.

7.6.2. Design and Tender

Methodology Review and Selection

The understanding of physical and chemical site conditions should be used to develop a comprehensive program. Various sediment removal alternatives should be evaluated to identify the preferred approach taking into consideration:

- Excavation (Conventional and/or Hydraulic);
- Dewatering (Drying Beds / Geo-Synthetic Bags / Belt Filter Press / Centrifuge); and,
- Disposal of Dewatered Sediments (On-site / Offsite).

The "preferred solution" will base on the best possible fit of removal and disposal methodologies under the existing conditions at each location and consider:

- Duration;
- Construction and equipment access;
- Work hours;
- Stockpiling of removed sediments;
- Pond dewatering;
- Sediment quality sampling;
- Disposal route;
- Odour Impact;
- Noise Impact;
- Aesthetic Impact; and
- Overall Cost.

Sediment Removal Options

For sediment removal both mechanical as well as hydraulic dredging methods are available. Both methods carry their advantages and disadvantages.

Conventional Excavation

Different excavating machines could be deployed such as tracked or wheeled front loader, shovel, back hoe, and backfill blade or bulldozer. The method of sediment drying / dewatering is also a factor in the selection. The size of the pond and the physical properties of the sediments is a key factor in the selection of the excavating equipment. Conventional excavation is very economical where the pond has a possibility and capacity to drain. The pond is drained and sediments are left exposed for drying naturally or suitable methods are adopted for removal of moisture contents in addition to a natural drying process. Conventional excavation is very cost effective where noise, odour or aesthetics is not a sensitive issue. This is the most desirable option because of the ease of operation and cost implication. The down side is that a longer duration is required for drying of sediments and non-availability of the SWMF for its desired function during that period.

Hydraulic Excavation

Hydraulic dredging is the best way to remove sediments without draining the SWMFs. One (1) option available includes auger dredging with an adjustable mud shield. These auger dredges are available in different sizes and are suitable for large volumes over longer distances. Dredges can be manoeuvred in the water by means of propellers, cables, or mechanical legs.

The auger dredge works by having an auger-like device cut into the sediments while, at the same time, a powerful pump is used to extract the resulting mixture of sediment and pond water. This changes the nature of the sediments from being semi-solid to be a slurry or “dredgeate”. The advantage of this situation is the slurry / dredgeate is relatively easy to pump from the floating dredge to a land based processing facility. The disadvantage is that extra water is required to create pumpable slurry and it must be removed before it is hauled away for disposal or reuse.

Sediment Dewatering

In order to determine a suitable dewatering site several aspects need to be investigated including:

- Proximity to the pond;
- Distance to the majority of dredging activities;
- Accessibility of large trucks;
- Adequacy of existing features and the magnitude of upgrading which would be required to provide all features needed for the dewatering equipment;
- Availability of power, and,
- Impact on land based environment and park users.

Settling Ponds / Conventional Drying Beds

Settling ponds offer the most cost effective and least noisy method available for the reduction of moisture content from the sediments. Disadvantages when using settling ponds include the duration, odour and aesthetics. Other options include conventional drying bed method. Available area for construction of drying ponds or bed is also an important factor to be considered for the selection of this method.

Geo-Synthetic Filter Bags

Geo-Synthetic Filter Bags are large bags made of very strong geo-fabric with maximum 500 microns filter opening. The dredgeate / slurry treated with flocculating compound is pumped into the filter bag. The fine sediments flocculate together and settle in the bag. Centrate is separated from dredgeate and filtered out of the filter bag. A constant head is maintained for expulsion of water from the filter bag (disposal of the centrate is a separate issue). The slurry is constantly pumped into the bag to keep a positive pressure on the escaping fluid. The bag is left for several days before more slurry is pumped into the bag. This process is repeated until the bag is full of sediment. The sediment filled bag is pierced and the sediments are disposed off at site or off site using conventional methods.

This method can be slow and the drying time is dependent upon the physical properties of the sediments, weather, surface area exposed to atmosphere, flocculating agent used, and area available for the filter bags (more filter bags means less dewatering time).

Mechanical Dewatering

These processes are already in use at waste water treatment facilities for the dewatering of sludge. The commonly used equipment is a plate and frame filter press, belt filter press and centrifuge.

The plate and frame filter press is a batch process, removal of moisture content is highest, dry solid content are in the range of 30 % to 52 %, disadvantage is intermittent operation and low production. The belt filter press is a labour intensive continuous operation. The resultant solid contents are up to 25 % and the production is low.

The centrifuge has an advantage of continuous operation with a high production rate. In water treatment and wastewater treatment industry, centrifuges are common at large treatment plants where high production rates, cleanliness and odour control (easier because centrifuge is mostly closed) are important. Centrifuges are most cost effective ($/ton processed) than any other process described above. The disadvantages of mechanical dewatering are cost, noise and power requirements.

Centrate Handling

It is anticipated if mechanical dewatering is selected; polymers will be used to accelerate the flocculation process. Once dredgeate is separated into residual solid content and centrate, some form of “polymer quenching” will be required before the water is returned to the pond.

Tender Documents

Tender documents should include all forms of tender, contract price schedules and contractual schedules such as, “General and Supplementary Conditions”, “Special Provisions”. It should address project specific items such as:

- Location plan;
- Site access routes;
- Construction area restriction plans showing staging and storage areas
- Erosion and silt protection;
- Excavation volumes;
- Bathymetric surveys;
- Existing and proposed typical cross-sections,

- Sediment quality;
- Dewatering techniques;
- Disposal methodologies;
- Material specifications and sundry construction;
- Retrofit / repairs to the existing components of the pond structure; and,
- Rehabilitation of eroded banks.

Construction methodology plans and details:

- Erosion and sediment control plans and project schedule and sequencing details;
- Site restoration plans (including seeding / sodding, erosion control matting, etc.);
- Landscaping (including bioengineering and habitat features) plans and details;
- Restoration Plans, Details and Specifications for hard and soft site elements;
- Detailed Cost Estimate, this includes for each pond site the accessibility of site, location of disposal, volume of sediment and quality of sediment;
- Flow bypass measures for period with rainfall;
- Short and long term monitoring requirement;
- Operations and Maintenance Manual; and,
- Detailed Design Report (including all documentation of calculations and recommendations).

7.6.3. Construction Supervision and Contract Administration

Tender and Award

The Tender and award process may involve Pre-Tender bidders meetings, responding to questions, preparing addenda, and contractor selection. Evaluation of construction bids should consider the ability of the contractor to complete the work within the specified timeframe, the cost, and the contractor's experience with pond projects and innovative or value added knowledge or technologies offered.

Pre-Construction

A Pre-Construction meeting should be held on-site to identify site specific constraints, work areas, staging areas and no disturbance areas. A detailed Pre-Construction survey, including digital pictures and videos, should be completed to document existing conditions. A Health and Safety audit should be conducted, with the results of the survey and audit should be included in the Pre-Construction Report.

Contract Administration and Construction Inspection Services

After a construction phasing and staging plan has been developed and a qualified contractor retained, it is important to develop and maintain a working construction scheduling document to track the progress of the construction and ensure that possible delays are minimized or avoided entirely. Environmental monitoring also plays an important role in managing risk to the Town during the construction period.

Sediment removal projects are often high public profile projects and communication between the field staff, contract administrators, project manager and the Town is critical. Periodic formal environmental inspections will occur during landscaping and at other times throughout the construction stages. Various specialists including a site inspector, environmental inspector and ecological specialists need to work together during the different stages of the program. Inspection services should include:

Contract administration and site inspections should include:

- Scheduling, co-ordinating and attending project review meetings including a pre-construction review meeting;
- Regular on-site inspections which include reporting;
- Liaising with the contractor and evaluating any out-of-scope requests;
- Ensuring that all environmental protection measures are acceptable and functioning as designed and identifying deficiencies to be corrected by the contractor;
- Maintaining a daily diary of construction events documenting the progress of the work and to substantiate the quality and quantity of the work performed;
- Providing comments to the contractor's proposed procedures, methods and construction phasing to ensure compliance with design and contract requirements;
- Managing claims, notices of intent to claim, disputes and questions relating to contractor performance, quality of the work and interpretation of the contract documents;
- Addressing inquires and request for information from external Agencies, adjacent landowners and members of the public; and,
- Reviewing and processing payment certification of Substantial and Total Performance for *Construction Lien Act* purposes.

Record Drawings and Project Completion

During the close-out period, close attention must be paid to the project documentation. In particular, any deficiencies must be identified, defined and the contractor notified. The deficiency must ultimately be rectified prior to the release of securities or other bonds supplied by the contractor. A final thorough review of the contract documents and the constructed works is required at this time. As-built conditions will be surveyed and design drawings updated to reflect the current conditions.

7.7. Maintenance

A summary of maintenance tasks for all ponds with at least one component ranking 3, 4 or 5 is provided below in **Table 7-2**.

Table 7-2 – Summary of Maintenance per Pond with Associated Cost

Pond ID	Component	Condition	Maintenance Task	Est. Cost
01	Facility	3	Prepare plan and remove sediment	$120,000.00
	Outlet	3	Fill in Erosion	$250.00
02	Grate	3	Refasten grating to headwall	$425.00
03	Inlet	3	Clean up debris and vegetation	$400.00
05	Facility	3	Remove debris	$800.00
	Grate Outlet	3	Clean up debris and vegetation	$400.00
06	Vegetation	3	Remove / Replace dead vegetation	$800.00
	Culvert	3	Cover Graffiti	$500.00
07	Grate	3	Grate cleanup	$200.00
	Outlet	4	Clean up debris and vegetation	$900.00

Pond ID	Component	Condition	Maintenance Task	Est. Cost
	Vegetation	3	Remove / Replace dead vegetation	$400.00
08	Facility	3	Prepare plan and remove sediment	$213,100.00
	Inlet	3	Add a grate to structure	$2,500.00
	Vegetation	3	Remove / Replace dead vegetation	$400.00
10	Grate	3	Lock grate	$200.00
	Facility	3	Prepare plan and remove sediment	$199,800.00
11	Vegetation	3	Remove / Replace dead vegetation	$4,000.00
	Fence	3	Repair broken links and fence supports	$400.00
	Headwall	3	Paint over graffiti	$500.00
	Fence	3	Repair broken links	$425.00
	Fence	3	Repair broken links and fence supports	$400.00
	Intermediate Quantity Inlet	3	Clean up debris and vegetation	$400.00
12	Sanitary Manhole	3	Investigate location	$200.00
14	Grate	3	Refasten grating to headwall	$400.00
15	Fence	3	Repair broken links and fence supports	$425.00
16	Facility	3	Continue Trapping Efforts	$1,000.00
	Manhole	3	Clean Debris from manhole	$3,000.00
	Inlet 3	3	Clean up debris and vegetation	$400.00
17	Facility	3	Prepare plan and remove sediment	$44,500.00
18	Facility	3	Remove debris	$400.00
	Outfall	3	Clear Debris	$400.00
19	Quality Outlet	3	Repair structure.	$3,000.00
	Vegetation	3	Remove / Replace dead vegetation	$800.00
20	Inlet	3	Fill in erosion.	$500.00
21	Facility	3	Perform spring inspection	$250.00
	Headwall	3	Clear Graffiti	$450.00
	Inlet	3	Cover graffiti.	$450.00
	Outlet	3	Clear Structures of any debris	$400.00
	Outlet Manhole	3	Clear Vegetation	$3,000.00
22	Inlet	3	Sample water to determine quality.	$700.00
23	Gate	3	Replace lock on structure.	$225.00
24	Pipe	4	Clean up debris, sediment and vegetation	$800.00
25	Vegetation	3	Remove / Replace dead vegetation	$800.00
26	Vegetation	3	Remove / Replace dead vegetation	$800.00
	Headwall	3	Paint over graffiti	$500.00

Condition rankings are further explained in **Section 7.4.3**. The cost associated with the maintenance required by each pond has been generated by SWMSoft based on the resource cost listed above in **Table 7-2**. It is noted that the cost associated with the above noted improvements are to be confirmed by the Town and may be updated within the SWMSoft software. The SWMSoft Inspection Report and Bathymetric Surveys is included in **Appendix L**.

7.7.1. Potential Improvements

This section discusses the common findings and recommendations across the SWMFs.

Unlocked Grates and Hatches

A large number of grates covering inlet and outlet pipes and hatches are not secure and pose a safety hazard. These grates should either be locked or bolted shut to prevent entry and remove the safety hazard. Bolting grates shut is the preferred method of securing the grates to avoid the need to manage the keys to all of the locks at different facilities.

Graffiti

Graffiti is a common aesthetic issue at SWMFs, and is most commonly found on concrete surfaces such as the headwalls of inlets and outlets. The recommended solution is to paint over the graffiti with grey paint, which is cost effective and obscures the graffiti. It is also possible to sand blast the concrete to remove the graffiti, however this would be more costly and may require the notification of homeowners in the surrounding area because of the noise and dust that would be created during the removal.

Litter

Litter is another common problem at SWMFs, and it can affect the facility's water quality as well as its aesthetics. The recommended solution is to dispatch Town work crews to remove the debris. In addition, the Town may consider placing additional garbage cans at the locations where litter is a recurring problem.

Vegetation

Overgrown vegetation at the inlet and outlets is a common problem at SWMFs, and can compromise the facility's function in controlling water levels. The recommended solution is to remove the overgrowth using hand tools.

Dead vegetation presents a problem in terms of aesthetics. It also poses as a possible safety risk if the tree is in danger of falling, or acts as a potential tripping hazard. Dead vegetation that presents a hazard should be removed and the area should be revegetated.

Beaver Damage

Several SWMFs show evidence of beaver damage. The presence of a beaver in the vicinity of a SWMF is a concern because the beaver may cause damage to surrounding vegetation or construct a dam that inhibits the proper function of the SWMF. Possible solutions to this problem are to either remove the beaver from the facility, or to place barriers that prevent the beaver from obstructing the flow of water.

The recommended solution is to hire a trapper licensed by the Ontario Ministry of Natural Resources (OMNR) to remove the beaver because the costs associated with installing and maintaining the barriers is greater than the cost to remove the beaver. Once the beaver is removed, prevention measures should be implemented to discourage beavers from inhabiting the facility in the future (Town of Richmond Hill, 2010).

Beaver dam removal is generally done using hand tools or equipment such as backhoes after the beaver is removed. The removal of the dam must be done carefully as it can negatively impact fish and fish habitat by decreasing the water level upstream of the dam, as well as releasing sediment and large volumes of water downstream (Fisheries and Oceans Canada 2010). Removal practices must follow the Fisheries and Oceans Canada – Ontario Operational Statement (2010) and avoid contravention with subsection 35(1) of the *Fisheries Act*: "*No person shall carry on any work or undertaking that results in the harmful alteration, disruption or destruction of fish habitat*".

If the conditions of the Operational Statement for beaver dam removal cannot be met, then the LSRCA should be contacted to discuss removal options to remain in compliance with the *Fisheries Act*.

Algae Blooms

Algae blooms, or rapid and excessive growth of algae, commonly occur in ponds. Algae blooms occur when conditions are extremely favourable to the growth of algal populations; these conditions include excess nutrients, low dissolved oxygen levels, and an abundance of sunlight. As algal blooms decompose, they remove a large amount of dissolved oxygen from the pond. The lack of oxygen can result in damage to the pond's ecosystem, and the decline of biota in the pond. Algal blooms are also unsightly, can cause foul odours, and negatively affect the water quality of the ponds (Clark 2008).

There are a number of different ways to control the algae population of a pond and prevent algae blooms from forming.

The most common methods involve killing the algae, limiting the amount of sunlight that enters the pond, and increasing the oxygen levels of the pond (Lynch 2009). Increasing the dissolved oxygen content in the pond is an effective way to control algae populations by addressing the underlying cause, and can be achieved by placing aeration equipment in the pond. The increased oxygen levels prevent algae growth, and lessen the impact of algae decomposition on the surrounding ecosystem (Clark, 2008).

The recommended solution is to install a sub-surface aeration system in the ponds affected by algal blooms. Aeration systems are relatively easy to maintain and will effectively control the algae population in a pond. The aeration system would have to be wind powered, because of the limited or no access to power at most pond locations. Wind powered aeration systems are widely available and commonly used to aerate ponds.

7.8. Costs

7.8.1. Regular Maintenance

There are two (2) main categories of regular maintenance:

- Debris / vegetation removal; and,

- Minor repair.

Most of the debris and vegetation removal centres on the inlet and outlet structures and require half a day's worth of work for a crew of two (2) people. This has been assumed to cost approximately $400.00 for Town operation staff to complete. Minor repairs generally involve repairing baffle blocks, replacing grates in front of pipes or mending fences. These tasks were budgeted to take between one (1) and three (3) days, depending on the severity of the damage. Such items were estimated to cost between $1000.00 and $4000.00 each. For unassumed ponds, a cost of $200.00 was assigned to the facility to account for discussion for the coordination of repair efforts with the developers. It should be noted that a number of assumptions were made on the costs of improvements. The Town is required to update the cost summary as a function of SWMSoft before costing and implementing the improvements.

7.8.2. Sediment Removal

The cost of removing sediment depends on:

- Accessibility of the site;
- Location for disposal;
- Volume of sediment; and,
- Quality of sediment.

The cost for removing sediment can be low, approximately $100.00/$m^3$ if the site is easily accessible, the sediment can be disposed of locally, and an analysis of sediment quality passes the Guidelines for Contaminated Sites. However, as some municipalities have experienced, the cost can increase more than 30-fold, if the sediment does not pass the guidelines and must be disposed of in a registered landfill. In addition, costs for sediment removal are typically based on a weight or mass of material basis rather than a volume of material basis, and the density of sediments may vary. Note that measurements obtained in this study correspond to in-situ volume measurements under saturated conditions. As such, the volume-based cost estimates include an intrinsic factor of safety.

The initial observations of the facilities deemed suitable for sediment removal did not reveal any problems that would cause removal costs to increase by an appreciable amount.

Preliminary estimates therefore determine the approximate cost of removal by multiplying the volume of accumulated sediment by $100.00. An additional amount of $25,000.00 is applied to all sediment removal costs to cover the expense of preparing a sediment removal plan. The plan includes site and equipment selection, permits, transportation, and sampling.

7.8.3. Cost Summary

The cost that is associated with the maintenance of each pond outlined in **Table 7-3** has been calculated by SWMSoft. The costs are based estimated amounts for each task to be completed along with the cost of the crew and hours to complete the task. These amounts have been entered in by Cole Engineering but can be adjusted by the Town. A full description of the amounts associated with each task is outlined in below in **Table 7-3**.

Table 7-3 – Cost Summary of SWMSoft Resource

Resource	Description	Cost per Unit*	Unit
General Inspector	City staff to perform seasonal inspections.	250	Use
Fencing	Black vinyl covered fence	5	Foot
Riprap	8 inch stone used around inlet / outlet	150	Cu. Metre
Weeping tile	Weeping tile with sock	15	Metre
General Contractor	Non-specific contractor to do simple repairs outside scope of city labourers	1	Dollar
General Consultant	Non-specific consultant to assess various problems outside of city expertise	1	Dollar
City Official	Non-specific city employee to consult with local residents	1	Dollar
2 Person Crew	2 Person City Work Crew (8 Hours)	800	Day
3 Person Contract Crew	3 Person Contract Work Crew (10 hours)	3000	Day
Site Inspector	Performs advanced inspections	600	Use
Water Sampling	Generic company for testing water samples	700	Use
Front-end Loader	Standard Front-end loader for use with 2 Person City Work Crew	800	Day
Miscellaneous	Undefined materials to be allocated to task	1	Dollar
Engineer	City Engineer	50	Hour
Lock	A padlock	25	Use
Paint	Paint	50	Gallon
Soil	Soil to use as fill	10	Cu. Ft.
Erosion Fabric	Erosion fabric	10	Metre
Grass Seed	Grass seed	50	Kilogram
Fence Repair Contractor	A contractor to perform structural repairs on fences	250	Use
Buoy Rope	Rope to attach the buoy to the emergency station, as well as safety rope around the buoy	50	Use
Plastic Pipe Cap	A cap to cover plastic riser pipes	50	Use
Buoy	Red floating buoy	50	Use
Hazard Sign	A sign	100	Use
Pest Control [Beaver]	A pest control company	1000	Use
Plastic Pipe	Plastic piping	10	Foot
Hoop	Emergency equipment hoop	100	Use
Pest control	Removal of problem animals	1	Dollar
Grate	A grate to cover a large outlet pipe	1000	Use
Aeration Equipment	A sub-surface aerator powered by a windmill	2500	Use

* The unit costs listed are an estimated cost for the resources. It is recommended that the Town update the unit rates.

8.0 Development of Long List of Alternatives

8.1. General

In order to identify the solution that best encompasses the study's principles, goals and objectives a long list of alternatives was generated. The alternatives consider both existing and future land uses within the Town that consists of rural and urban areas.

The approach for developing and evaluating alternatives is consistent with the requirements of the planning and design process for Master Planning projects described in the Municipal Class EA (Municipal Engineers Association, June, 2000). It involves reviewing Phase One work (i.e. Identification of the Problem) and undertaking Phase Two (i.e. Establishing Existing Conditions, Identification of Long List of Alternatives, Development and Assessment of Alternative Management Strategies and Selection of a Preferred Strategy). In addition, consultation with stakeholders is a necessary step in this process.

8.2. Overview of Alternatives

A range of alternative solutions was developed in order to address the identified problem and opportunity. The alternatives identified for evaluation are summarized in the following categories:

- Source Controls;
- Conveyance Controls;
- End of Pipe Measures; and,
- Restoration Measures.

Even though the "Do Nothing" alternative does not address the Problem / Opportunity Statement, the Class EA document mandates its consideration in all Class EAs as a means of providing a benchmark for evaluating the other alternative solutions.

The following subsections briefly describe each of these alternative solutions.

8.2.1. Source Controls

This alternative involves physical measures that are located at the beginning of the drainage system; generally on private property. Source controls will reduce stormwater runoff generated from impervious surfaces that mostly occur in urban areas. Source controls can be used in a variety of different land uses such as residential, industrial and commercial. Source controls can be retrofitted into existing areas and implemented into proposed urban areas. Source control measures include:

Roof Downspout Disconnection

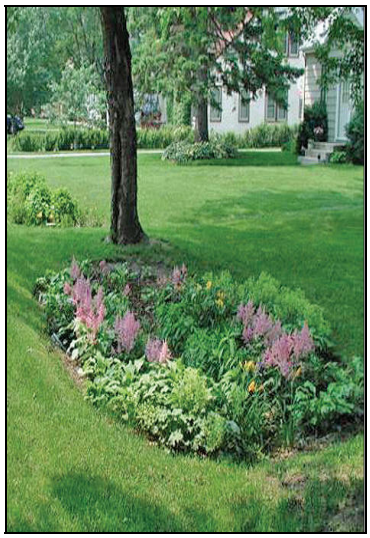
Simple downspout disconnection involves directing flow from roof downspouts to a pervious area that drains away from the building. This prevents stormwater from directly entering the storm sewer system or flowing across a "connected impervious surface, such as a driveway, that drains to a storm sewer. Simple downspout disconnection requires a minimum flow path length across the pervious area of 5 metres.

When the infiltration rate of the soil in the pervious area is less than 15 mm/hr (i.e. hydraulic conductivity of less than $1x10^{-6}$ cm/s), the area should be tilled to a depth of 300 mm and amended with compost to achieve an organic content in the range of 8 to 15% by weight or 30 to 40% by volume.

Bioretention

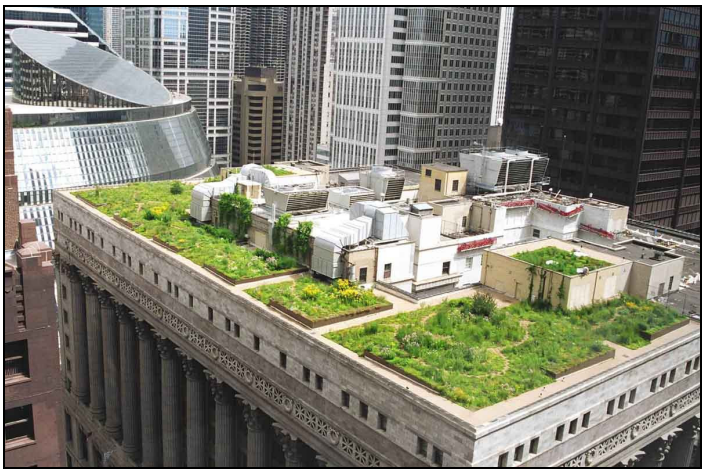
As a stormwater filter and infiltration practice, bioretention temporarily stores, treats and infiltrates runoff. Depending on native soil infiltration rate and physical constraints, the system may be designed without an underdrain for full infiltration, with an underdrain for partial infiltration, or with an impermeable liner and underdrain for filtration only, which can also be referred to as a biofilter. The primary component of a bioretention practice is the filter bed which is a mixture of sand, fines and organic material. Other important elements of bioretention include a mulch ground cover and plants adapted to the conditions of stormwater practice. Pretreatment, such as a settling forebay, vegetated filter strip, or stone diaphragm, often precedes the bioretention to remove particles that would otherwise clog the filter bed. Bioretention is designed to capture small storm events or the water quality storage requirement. An overflow bypass is necessary to pass large storm events.

Bioretention can be adapted to fit into many different development contexts and provides a convenient area for snow storage and treatment. In a low density development, it might have a soft edge and gentle slopes, while a high density application might have a hard edge with vertical slopes.



Green Roofs (i.e. Roof Gardens)

Green roofs, also known as "living roofs" or "rooftop gardens", consist of a thin layer of vegetation and growing medium installed on top of a conventional flat or sloped roof. Green roofs are publicized for their benefits to cities, as they improve energy efficiency, reduce urban heat island effects, and create greenspace for passive recreation or aesthetic enjoyment. To a water resources manager, they are attractive for their water quality, water balance, and peak flow control benefits. From a hydrologic perspective, the green roof acts like a lawn or meadow by storing rainwater in the growing medium and ponding areas. Excess rainfall enters underdrains and overflow points and is conveyed in the building drainage system. After the storm, a large portion of the stored water is evapotranspirated by the plants, evaporates or slowly drains away.



Soakaway Pits, Infiltration Trenches and Chambers

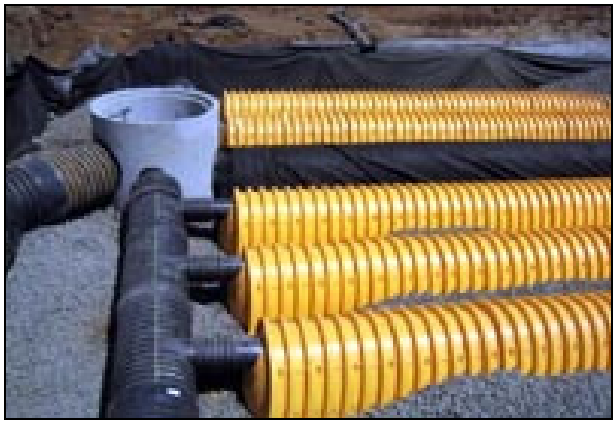
On sites suitable for underground stormwater infiltration practices, there are a variety of facility design options to consider, such as soakaway pits, infiltration trenches and infiltration chambers.

Soakaway pits are rectangular or circular excavations lined with geotextile fabric and filled with clean granular stone or other void forming material, which receives runoff from a perforated pipe inlet and allow it to infiltrate into the native soil. They typically service individual lots and receive only roof and walkway runoff but can also be designed to receive overflows from rainwater harvesting systems. Soakaways can also be referred to as infiltration galleries, dry wells or soakaway pits.

Infiltration trenches are rectangular trenches lined with geotextile fabric and filled with clean granular stone or other void forming material. Like soakaways, they typically service an individual lot and receive only roof and walkway runoff. This design variation on soakaways is well suited to sites where available space for infiltration is limited to narrow strips of land between buildings or properties, or along road rights-of-way. They can also be referred to as infiltration galleries or linear soakaways.

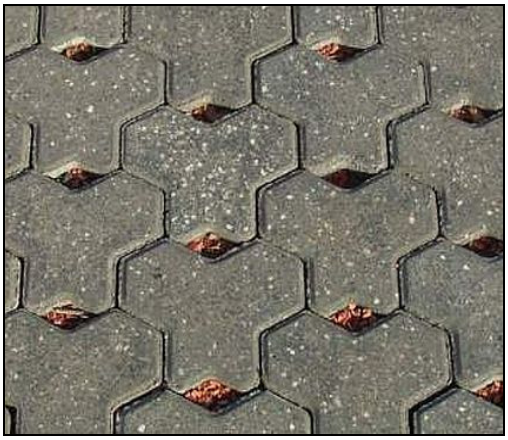
Infiltration chambers are another design variation on soakaways.

They include a range of proprietary manufactured modular structures installed underground, typically under parking or landscaped areas that create large void spaces for temporary storage of stormwater runoff and allow it to infiltrate into the underlying native soil. Structures typically have open bottoms, perforated side walls and optional underlying granular stone reservoirs. They can be installed individually or in series in trench or bed configurations. They can infiltrate roof, walkway, parking lot and road runoff with adequate pretreatment. Due to the large volume of underground void space they create in comparison to a soakaway of the same dimensions, and the modular nature of their design, they are well suited to sites where available space for other types of BMPs is limited, or where it is desirable for the facility to have little or no surface footprint (e.g., high density development contexts). They can also be referred to as infiltration tanks.



Permeable Pavement

Permeable pavements, an alternative to traditional impervious pavement, allow stormwater to drain through them and into a stone reservoir where it is infiltrated into the underlying native soil or temporarily detained. They can be used for low traffic roads, parking lots, driveways, pedestrian plazas and walkways. Permeable pavement is ideal for sites with limited space for other surface stormwater BMPs. Depending on the native soils and physical constraints, the system may be designed with no underdrain for full infiltration, with an underdrain for partial infiltration, or with an impermeable liner and underdrain for a no infiltration or detention and filtration only practice. Permeable paving allows for filtration, storage, or infiltration of runoff, and can reduce or eliminate surface stormwater flows compared to traditional impervious paving surfaces like concrete and asphalt.



Rainwater Harvesting (i.e. Rain Barrels, Cisterns, etc.)

Rainwater harvesting is the process of intercepting, conveying and storing rainfall for future use. Harvesting rainwater for domestic uses has been practical in rural Ontario for well over a century. Interest in adapting this practice to urban areas is increasing as it provides combined benefits of conserving potable water and reducing stormwater runoff. When harvested rainwater is used to irrigate landscaped areas, the water is either evapotranspirated by vegetation or infiltrated into the soil, thereby helping to maintain predevelopment water balance.

8.2.2. Conveyance Controls

This alternative involves controlling stormwater as it travels along the drainage system. The Town contains a variety of existing drainage paths that would lead to retrofitting opportunities or with evaluation, the opportunity for new drainage paths. The goal of this alternative is to reduce erosion and storm water runoff. Conveyance controls can consists of swales, ditches, culverts, catch basins, manholes, and storm sewers. Some conveyance control measures include:

Grassed Swales

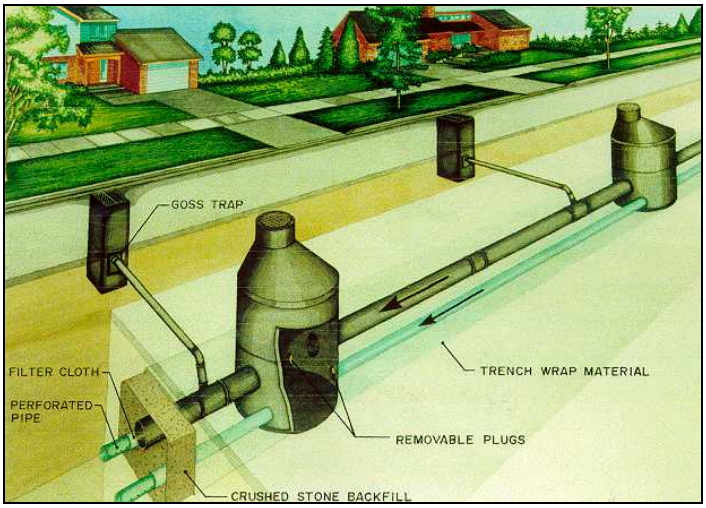
Grassed swales are vegetated open channels designed to convey, treat and attenuate stormwater runoff (also referred to as enhanced vegetated swales). Check dams and vegetation in the swale slows the water to allow sedimentation, filtration through the root zone and soil matrix, evapotranspiration, and infiltration into the underlying native soil. Simple grassed channels or ditches have long been used for stormwater conveyance, particularly for roadway drainage.

Grassed swales incorporate design features such as modified geometry and check dams that improve the contaminant removal and runoff reduction functions of simple grassed channel and roadside ditch designs. A dry swale is a design variation that incorporates an engineered soil media bed and optional perforated pipe underdrain system. Grassed swales are not capable of providing the same water balance and water quality benefits as dry swales, as they lack the engineered soil media and storage capacity of that best management practice.

Perforated Pipe Systems

Perforated pipe systems can be thought of as long infiltration trenches or linear soakaway pits that are designed for both conveyance and infiltration of stormwater runoff. They are underground stormwater conveyance systems designed to attenuate runoff volume and thereby, reduce contaminant loads to receiving waters. They are composed of perforated pipes installed in gently sloping granular stone beds that are lined with geotextile fabric that allow infiltration of runoff into the gravel bed and underlying native soil while it is being conveyed from source areas or other BMPs to an end-of-pipe facility or receiving waterbody. Perforated pipe systems can be used in place of conventional storm sewer pipes where topography, water table depth, and runoff quality conditions are suitable.

They are suitable for treating runoff from roofs, walkways, parking lots and low to medium traffic roads, with adequate pretreatment. A design variation can include perforated catchbasins, where the catchbasin sump is perforated to allow runoff to infiltrate into the underlying native soil. Perforated pipe systems can also be referred to as pervious pipe systems, exfiltration systems, clean water collector systems and percolation drainage systems.



Vegetated Filter Strips

Vegetated filter strips (i.e. buffer strips and grassed filter strips) are gently sloping, densely vegetated areas that treat runoff as sheet flow from adjacent impervious areas. They function by slowing runoff velocity and filtering out suspended sediment and associated pollutants, and by providing some infiltration into underlying soils. Originally used as an agricultural treatment practice, filter strips have evolved into an urban SWM practice. Vegetation may be comprised of a variety of trees, shrubs and native plants to add aesthetic value as well as water quality benefits. With proper design and maintenance, filter strips can provide relatively high pollutant removal. Maintaining sheet flow into the filter strip through the use of a level spreading device is essential.

8.2.3. End of Pipe Measures

This alternative consists of managing stormwater at the end of a storm sewer system prior to discharging to a stream.

They usually consist of man-made measures such as stormwater ponds or constructed wetlands. This alternative would look at opportunities for retrofit of existing ponds, or if there is a need for more. End of pipe measures include Best Management Practices.

SWM Ponds (i.e. Wet Ponds)

Wet ponds are the most common end-of-pipe SWMF employed in Ontario. They are less land-intensive than wetland systems and are normally reliable in operation, especially during adverse conditions (e.g., winter / spring).

This reliability can be attributed to:

- Performance does not depend on soil characteristics;
- The permanent pool minimizes re-suspension;
- The permanent pool minimizes blockage of the outlet;
- Biological removal of pollutants occurs (including phosphorus); and,
- The permanent pool provides extended settling.

Wet ponds can be designed to efficiently provide for water quality, erosion and quantity control, reducing the need for multiple end-of-pipe facilities. Wet ponds can be designed with extensive landscaping and associated recreational amenities, contributing to the character of the community and enhancing its marketability.

Dry Ponds

Dry ponds have no permanent pool of water. As such, while they can be effectively used for erosion control and flood control, the removal of stormwater contaminants in these facilities is purely a function of the detention time in the pond. For a 24 hour retention period, this normally means a lower contaminant removal (the inter-event settling time does not exist). While achieving this for smaller drainage areas can be difficult (because of orifice size considerations), the use of dry ponds in larger catchments (especially in retrofit situations) may have greater potential than had previously been thought. There are no documented performance monitoring data for dry ponds with longer detention times, however, and re-suspension of settled material remains a concern. As such, the use of dry ponds (for water quality control) remains largely restricted to retrofits, where temperature is an overriding concern, and situations where other more effective SWMP types are infeasible. Dry ponds may be used as part of an overall treatment train approach.

Constructed Wetlands

The constructed wetland is one of the preferred end-of-pipe SWM facilities for water quality enhancement. Wetlands are normally more land-intensive than wet ponds because of their shallower depth (both in the permanent pool and in the active storage zone). They are suitable for providing the storage needed for erosion control purposes, but will generally be limited in their quantity (i.e. flood) control role because of the restrictions on active storage depth.

Benefits of constructed wetlands are similar to wet ponds and include:

- Performance does not depend on soil characteristics;
- The permanent pool minimizes re-suspension;
- The permanent pool minimizes blockage of the outlet;
- Biological removal of pollutants occurs (including phosphorus); and,
- The permanent pool provides extended settling.

8.2.4. Restoration Measures

This would include the restoration or enhancement of existing habitats, both rural and urban within the Town. Stream Restoration Programs, Aquatic Habitat Enhancement and Terrestrial Habitat Enhancement are examples of restoration measures that attenuate erosion and promote infiltration.

8.2.5. Rural Measures

East Gwillimbury has a large percentage of land dedicated to rural uses. This alternative is simply Best Management Practices aimed for rural properties. There are structural based and non-structural based practices.

Structural Best Management Practices: Aimed to reduce runoff and pollution from agricultural practices this would include proper manure storage and handling, feedlot runoff controls, and internal wetland systems to control feedlot runoff and milkhouse wastes.

Non-Structural Best Management Practices for Rural Areas: Includes livestock fencing, buffer strips, conservation tillage and nutrient management. These measures would address non-point pollution sources.

9.0 Development and Assessment of Alternative Solutions

9.1. Identification / Description of Alternative Solutions

As an initial step, the Project Team identified and described alternative solutions, or functionally different ways of addressing the problem / opportunity statement, as described in **Section 1.6**. Any "reasonable" alternative was included initially. All alternatives were considered equally for discussion purposes and evaluation as seen in **Section 10.0**.

9.2. General

The development of Alternative SWM Strategies is necessary in order to determine the effectiveness of each strategy with respect to protecting, enhancing and restoring the natural resources of the watersheds located within the Town under existing and planned land use changes.

For the purposes of the SWMMP, a SWM Strategy was defined as a set of BMPs which, when implemented collectively, will attempt to address impacts associated with change in land uses within the watersheds. The land uses under consideration include existing urban and rural land uses and proposed development within the settlement areas.

The assessment was undertaken using results from the modelling as well as taking into account various factors such as social, economic and environmental criteria which are defined to further develop specific components of the Alternative Strategies. In addition, the assessment will look to find an alternative which minimizes, to the extent possible, the impact on the community, natural environment and the economy.

The approach used for developing and evaluating alternatives is, where appropriate, consistent with the planning and design process for Master Planning projects as described in the Class EA document. The approach has been used for measures which are located outside proposed development areas (i.e. stream restoration works, stormwater pond retrofit works).

For other measures, such as the construction of SWM measures for proposed developments, or the implementation of a Town wide program (i.e. disconnection of roof downspouts) general direction as to the types of measure, or proposed programs will be provided in each alternative.

9.3. Development of Alternative SWM Strategies

The Town is comprised of mainly rural area. The Protected Countryside, which includes the Oak Ridges Moraine and Greenbelt Plan, represents approximately 75% of the Town's land area.

Results from the Existing Conditions as assessed in **Section 3.0** indicate the existing environmental conditions are not meeting the requirements as set out in the Lake Simcoe Protection Plan.

The assessment of existing conditions suggest that the Alternative Management Strategies, if they are to be affective, must deal with impacts associated with the existing urban and rural land uses as well as proposed land uses. In addition, the problem statement identifies the need to improve the SWM within existing developments as well as planned. The strategies must also incorporate the principles of the Lake Simcoe Protection Plan, specifically Section 4.8-DP and the requirements regarding phosphorus removal and mitigation of changes in water balance.

A total of five (5) Alternative Management Strategies have been brought forward for assessment. The five strategies are defined as:

1. Do Nothing;
2. Traditional SWM Strategy;
3. Traditional SWM with BMP Implementation Strategy;

4. Traditional SWM with Urban Retrofits Strategy; and,
5. Traditional SWM with Rural Retrofits Strategy.

Table 9-1 below has been developed to summarize the potential effects of each alternative with respect to flow volume, phosphorus loadings, infiltration reduction and erosion potential. These impacts would occur within the Town as a result of the proposed land use change.

9.3.1. Do Nothing

The "Do Nothing" alternative would involve leaving the Town as is. No SWM works are carried out in any of the existing urban or rural lands or within any proposed development or redevelopment areas. An assessment to the impacts associated with the implementation of this strategy is required as part of undertaking a Municipal Class Environmental Assessment Study.

As seen in **Table 9-1**, this strategy would result in higher flow volumes, increased flooding, increase production of phosphorus, an increase in erosion potential and infiltration reduction.

9.3.2. Traditional SWM Strategy

The Traditional SWM Strategy is the implementation of SWM in proposed development or redevelopment areas. The SWM works would consist of the construction of SWM ponds for quantity, quality and erosion control as per MOE guidelines demonstrate.

Proposed developments would be serviced by conventional storm sewer systems and limited source control measures would be implemented such as downspout disconnection.

This alternative would result in higher flow volumes, an increase in erosion potential, and an increase in production of phosphorus and infiltration reduction.

9.3.3. Traditional SWM with BMP Implementation Strategy

This Strategy is consistent with the Traditional SWM Strategy as it will apply to proposed development and redevelopment areas. A variety of BMP source controls, conveyance controls and end-of-pipe measures will be implemented for all proposed areas of development. Alternative developments (i.e. LEED certified developments, Low Impact Developments) would also be considered.

A series of assumptions for the types of Best Management Practices to be implemented with this Strategy were made in order to include this Strategy as an Alternative. The types of BMP measures to be implemented are further explained in **Section 8.2**.

9.3.4. Traditional SWM with Urban Retrofits Strategy

This strategy is consistent with the Traditional SWM Strategy in that conventional SWM strategies would be implemented within proposed development or redevelopment areas. In addition to traditional SWM, a variety of source, conveyance and end-of-pipe measures will be implemented in existing urban areas.

This strategy is highly based on the amount of participating landowners to implement the proposed retrofits at the source level. The types of urban retrofits to be implemented in this strategy are further explained in **Section 8.2**.

9.3.5. Traditional SWM with Rural Retrofits Strategy

This strategy is consistent with the Traditional SWM Strategy in that conventional SWM strategies would be implemented within proposed development or redevelopment areas. In addition to traditional SWM, a variety of source, conveyance and end-of-pipe measures will be implemented in existing rural areas.

Similar to the Traditional SWM with Urban Retrofit Strategy, rural retrofit implementation is also based on the amount of participating rural landowners to implement the proposed retrofits at the source level. The types of rural retrofits to be implemented in this strategy are further explained above in **Section 8.2.5**.

Table 9-1 – SWM Strategy Alternatives

Preliminary Criteria	SWM Strategy Alternatives				
	Do Nothing	Traditional	Traditional w / BMPs	Traditional w / Urban Retrofits	Traditional w / Rural Retrofits
Land Uses where Strategy is to be Applied	None	Proposed Development and Redevelopment Areas	Proposed Development and Redevelopment Areas	Proposed Development and Redevelopment Areas and Existing Urban Areas	Proposed Development and Redevelopment Areas and Existing Rural Areas
Flows	Increase in Runoff	Increase in Flow Volume	Reduction in Flow Volume	Reduction in Urban Areas	Reduction in Rural Areas
Phosphorus Loading	Current Condition	Increase	Reduction	Reduction in Urban Areas	Current Condition in Urban Areas Reduction in Rural Areas
Infiltration	Current Condition	Reduction	Increase	Increase in Urban Areas	Current Condition
Erosion Potential	Current Condition	Increase	Reduction	Reduction in Urban Areas	Current Condition

9.4. Development of Evaluation Categories and Criteria

Evaluation criteria were developed to reflect the definition of “environment” provided in the OEAA and the specific circumstances associated with this project. Criteria that were considered were divided into categories, as listed below in **Table 9-2**.

Table 9-2 – Preliminary Evaluation Criteria

Technical
Opportunity to reduce peak flows into Lake Simcoe
Opportunity to decrease erosion of watercourses
Opportunity to improve water quality
Opportunity to reduce phosphorus loadings into Lake Simcoe
Opportunity to mitigate changes in water balance
Natural Heritage Features
Provisions of direct and indirect fish habitat
Potential to improve terrestrial habitats
Impacts to natural hazard features
Social Environment
Ability to improve public health and safety
Impacts to private properties
Impacts to public property
Cultural Environment
Impacts to built and cultural heritage landscape
Impacts to archaeological resources
Economic Environment
Capital costs
Operation and Maintenance costs
Risk management
Impact on agricultural land use

It is noted that the evaluation criteria was applied on an individual settlement area basis where the key implementations of the alternative SWM strategies could be effectively applied. The preferred alternatives for each settlement area are based on existing site constraints and the feasibility of implementing SWM improvements to each area. The preferred alternative strategy is outlined in **Section 10.0**.

10.0 Preferred Alternative Strategy

The preferred alternative strategy is to provide site specific recommendations on a settlement area basis where growth is expected to occur as part of the Town Consolidated Official Plan 2031. The following sections detail the preferred alternative within each settlement area, the opportunities and constraints associated in the implementation of the strategy and information inclusive to future developments within each settlement area. In addition, a summary of the site specific criteria is provided for each settlement area. It is noted the recommendations provided are indicative of the Master Plan process and that future developments require detailed analysis of existing site conditions and approval by the LSRCA and other approval agencies before implementing any recommendations described herein.

10.1. Site Specific Recommendations

Based on existing conditions, the Town's OP, and the results of **Section 4.0**, recommendations and criteria for each settlement area have been developed.

10.1.1. Mount Albert

General

It is proposed within the Community of Mount Albert, a small amount of growth will occur in the projected future. The existing land use is 12% imperviousness and the area is planned to develop which will lead to a 10% increase. This increase is due to the addition of an employment area and some institutional designated land.

It is important to note that within this settlement boundary there are areas of high aquifer vulnerability and wellhead protection areas that should be avoided when attempting to infiltrate stormwater runoff (**Figure 4-8**). The Region of York Official Plan should be consulted when determining the regulations surrounding the implementation of SWM ponds (Region of York 2010). There are also several erosion sites in Mount Albert, specifically along the Mount Albert Creek. Controlling stormwater will help to mitigate erosion by reducing peak flows, but other measures such as adding riparian vegetation may need to be considered and can also help reduce phosphorus loading.

Three (3) SWM facilities are proposed to handle stormwater from new developments. Feasible locations are outlined above in **Figure 4-8**. Proposed SWM facilities should be located outside of the floodplain and 2-year wellhead protection zones. It should be noted these ponds will have to undergo a detailed design process as discussed in **Section 4.3.7**. It is recommended that the Town monitor groundwater levels to allow for measures such as infiltration trenches.

Quantity Control

As discussed in **Section 4.3.7**, quantity control should be enforced using "post-to-pre" criteria with the exception of the drainage areas outlined in **Table 4-42** in which unit-flow rates should be applied.

Quality Control

Stormwater quality control should be enforced using Ministry of Environment criteria and developments should provide 80% TSS Removal and Enhanced water quality levels.

As discussed in **Section 4.4**, stormwater quality control in terms of phosphorus control in the Mount Albert settlement area should be enforced using criteria of a total phosphorus removal rate of 3.78 kg/year/ha.

Water Budget

As discussed in **Section 4.5**, in order to maintain the existing infiltration rates, future developments will require to maintain an infiltration rate of 3025 m^3/ha within the Mount Albert settlement area.

Best Management Practices

Recognizing that Mount Albert consists mainly of well draining soils, BMPs such as infiltration trenches and infiltration galleries may be implemented for new developments. For existing rural areas, it is recommended rural BMPs be considered were applicable.

The stormwater management criteria and recommendations for the Mount Albert settlement area are summarized in **Table 10-1** below.

Table 10-1 – Mount Albert Recommendation Summary

Quantity Control	Water Quality	Water Budget	Best Management Practices
▪ Post development flows to be controlled to pre-development peak flow rates ("post-to-pre") ▪ Unit-flow rates as summarized in **Table 4-42** are to be applied for specific drainage areas in Mount Albert	▪ Water quality is to be controlled to Enhanced levels (i.e. 80% TSS removal). ▪ A required phosphrous removal rate of 3.78 kg/year/ha is required for the Mount Albert settlement area.	▪ A required infiltration rate of 3025 m^3/ha is required for the Mount Albert settlement area.	▪ It is recommended that infiltration measures and Rural BMPs, including livestock fencing and buffer strips, be implemented where applicable.

It should be noted that all requirements of the SWM guidelines should be met. The SWM guidelines can be found in **Section 12.1.4**.

Preferred SWM Strategy

Based on the above, the preferred SWM strategy for Mount Albert is the *Traditional SWM with BMP Implementation Strategy in combination with Traditional SWM with Rural Retrofits Strategy*. Retrofit opportunities are further discussed in **Section 7.0** and illustrated above in **Figure 3-5**. Where applicable, it is recommended to provide BMPs in areas where soils and groundwater levels permit on a future development basis. A figure of the constraints and opportunities for the implementation of BMPs located within Mount Albert is provided above as **Figure 4-8**.

10.1.2. Queensville

General

The Queensville area will see some large changes in growth by 2031 according to the Town of East Gwillimbury Consolidated Official Plan. Queensville is currently mainly an agriculture area containing a small amount of residential land with 3% imperviousness. It plans to grow to a multi-functional area with prestige employment areas, medium density and low density residential, as well as a village core area. The future settlement area will be approximately 21% imperviousness. The area contains all four (4) types of soil, but is less than half well draining soils. In addition, there is a large area that is designated wellhead protection area.

There are no existing SWM facilities in Queensville and it is recommended that future SWM facilities that will service this area should comply with Lake Simcoe Protection Plan guidelines for quality and quantity control. Four (4) ponds have been proposed based on the expected growth of the area. Feasible locations are outlined above in **Figure 4-9**. Where SWM facilities cannot be built, (i.e. in wellhead protection areas and groundwater recharged zones), the implementation of site specific BMP's are recommended.

New SWM facilities are prohibited within the 2-year Wellhead Protection Zones as per the Region of York Official Plan (Region of York 2010). Within the Queensville settlement area there is also an area designated for Maskinonge River Significant Groundwater Recharge. It is important to note that this area can be directly connected to the groundwater supply hence stormwater BMP measures should only be implemented after additional analysis is completed.

There are no known erosion sites within this settlement area, but stream bank stability should be investigated to prevent future erosion due to the increase in growth and peak runoff.

Quantity Control

As discussed in **Section 4.3.7**, quantity control should be enforced using "post-to-pre" criteria with the exception of the drainage areas outlined in **Table 4-42** in which unit-flow rates should be applied.

Quality Control

Stormwater quality control should be enforced using Ministry of Environment criteria and developments should provide 80% TSS Removal and Enhanced water quality levels.

As discussed in **Section 4.4**, stormwater quality control in terms of phosphorus control in the Queensville settlement area should be enforced using criteria of a total phosphorus removal rate of 0.66 kg/year/ha.

Water Budget

As discussed in **Section 4.5**, in order to maintain the existing infiltration rates, future developments will require to maintain an infiltration rate of 1760 m^3/ha within the Queensville settlement area.

Best Management Practices

Recognizing that the Queensville settlement area consists mainly of poor draining soils, areas where SWM facilities cannot be built, site specific BMP's are recommended. It is recommended further investigation is required at a detailed level for areas where BMP's will be proposed.

The stormwater management criteria and recommendations for the Queensville settlement area are summarized in **Table 10-2** below.

Table 10-2 – Queensville Recommendation Summary

Quantity Control	Water Quality	Water Budget	Best Management Practices
Post development flows to be controlled to pre-development peak flow rates ("post-to-pre"). Unit-flow rates as summarized in **Table 4-42** are to be applied for specific drainage areas in Queensville.	Water quality is to be controlled to Enhanced levels (i.e. 80% TSS removal). A required phosphrous removal rate of 0.66 kg/year/ha is required for the Queensville settlement area.	A required infiltration rate of 1760 m^3/ha is required for the Queensville settlement area.	It is recommended to provide BMPs in areas where soils and groundwater levels permit on a future development basis.

It should be noted that all requirements of the SWM guidelines should be met. The SWM guidelines can be found in **Section 12.1.4**.

Preferred SWM Strategy

Based on the above, the preferred SWM strategy for Queensville is the *Traditional SWM with BMP Implementation Strategy*. Where applicable, it is recommended to provide BMPs in areas where soils and groundwater levels permit on a future development basis. A figure of the constraints and opportunities for the implementation of BMPs located within Queensville is provided above as **Figure 4-9**.

10.1.3. Holland Landing

General

Holland Landing is currently comprised mostly of low density residential, with some commercial and natural areas with an overall imperviousness of 17%. This settlement area will expand its residential and commercial land while maintaining a wetland and natural area. Imperviousness is expected to rise to approximately 23%. Holland Landing has a large area of well draining soils with a designated wellhead protection area in the southeast region.

The East Holland River flows north-south through Holland Landing and stream bank erosion and sedimentation is of concern in some areas. It is recommended to dredge areas that have been identified with sedimentation build up, and stabilize stream banks where erosion is of concern. These recommendations will assist in decreasing phosphorus loadings into the river and into Lake Simcoe.

Three (3) SWM facilities are proposed and illustrated in the constraints and opportunities figure for Holland Landing (**Figure 4-10**). It should be noted any new facilities are prohibited in the 2-year Wellhead Protection Zones as per the Region of York Official Plan (Region of York 2010) and their location will require further detailed analysis before implementation.

Quantity Control

As discussed in **Section 4.3.7**, quantity control should be enforced using "post-to-pre" criteria with the exception of the drainage areas outlined in **Table 4-42** in which unit-flow rates should be applied.

Quality Control

Stormwater quality control should be enforced using Ministry of Environment criteria and developments should provide 80% TSS Removal and Enhanced water quality levels.

As discussed in **Section 4.4**, stormwater quality control in terms of phosphorus control in the Holland Landing settlement area should be enforced using criteria of a total phosphorus removal rate of 12.1 kg/year/ha.

Water Budget

As discussed in **Section 4.5**, in order to maintain the existing infiltration rates, future developments will require to maintain an infiltration rate of 2892 m^3/ha within the Holland Landing settlement area.

Best Management Practices

Recognizing that Holland Landing consists mainly of well draining soils, it is recommended to provide BMPs in areas where soils and groundwater levels permit on a future development basis. It should be noted that Holland Landing is also highly urbanized and the implementation of BMPs will be subject to space restrictions.

The stormwater management criteria and recommendations for the Holland Landing settlement area are summarized in **Table 10-3** below.

Table 10-3 – Holland Landing Recommendation Summary

Quantity Control	Water Quality	Water Budget	Best Management Practices
Post development flows to be controlled to pre-development peak flow rates ("post-to-pre"). Unit-flow rates as summarized in **Table 4-42** are to be applied for specific drainage areas in Holland Landing.	Water quality is to be controlled to Enhanced levels (i.e. 80% TSS removal). A required phosphorus removal rate of 12.1 kg/year/ha is required for the Holland Landing settlement area.	A required infiltration rate of 2892 m^3/ha is required for the Holland Landing settlement area.	It is recommended to provide BMPs in areas where soils and groundwater levels permit on a future development basis.

It should be noted that all requirements of the SWM guidelines should be met. The SWM guidelines can be found in **Section 12.1.4**.

Preferred SWM Strategy

Based on the above, the preferred SWM strategy for Holland Landing is the *Traditional SWM with BMP Implementation Strategy* in combination with *Traditional SWM with Urban Retrofits Strategy*. Retrofit opportunities are further discussed in **Section 7.0** and illustrated above in **Figure 4-10**. Where applicable, it is recommended to provide BMPs in areas where soils and groundwater levels permit on a future development basis. A figure of the constraints and opportunities for the implementation of BMPs located within Holland Landing is provided above in **Figure 4-10**.

10.1.4. Sharon

General

Sharon Community is expected to expand into almost completely residential with 27% imperviousness from its current state which is approximately 19% impervious. According to the Sharon Community MESP (February 2010), there are low permeable soils present that will restrict the type of BMP measures put into place.

There are no identified erosion concerns within the settlement area but regular inspection should be completed for receiving watercourses to maintain good condition. There are no areas that have been identified as high aquifer vulnerability and only a very small portion that contains 10 year and 25 year zones of wellhead protection. In said areas, there are guidelines surrounding SWM Facilities but are expected to have minor impacts to planning efforts. Consultation of the Region of York Official Plan and Sharon Community MESP (February 2010) is recommended.

Existing SWM Facilities failing to meet Enhanced criteria should be upgraded according to the SWMSoft Maintenance Schedule detailed in **Section 7.0**. Two (2) ponds have been proposed based on land use and stormwater management restrictions and are illustrated in **Figure 4-11**. Further detailed study is recommended on a site specific basis for each new development.

Quantity Control

As discussed in **Section 4.3.7**, quantity control should be enforced using "post-to-pre" criteria with the exception of the drainage areas outlined in **Table 4-42** in which unit-flow rates should be applied.

Quality Control

Stormwater quality control should be enforced using Ministry of Environment criteria and developments should provide 80% TSS Removal and Enhanced water quality levels.

As discussed in **Section 4.4**, stormwater quality control in terms of phosphorus control in the Sharon settlement area should be enforced using criteria of a total phosphorus removal rate of 9.9 kg/year/ha.

Water Budget

As discussed in **Section 4.5**, in order to maintain the existing infiltration rates, future developments will require to maintain an infiltration rate of 3788 m^3/ha within the Sharon settlement area.

Best Management Practices

Recognizing that Sharon consists of mainly low permeable soils, BMPs such as infiltration-enhancing measures in addition to the use of infiltration trenches should be examined when additional site-specific information is available. BMPs such as infiltration trenches would fill and overflow quickly leaving the BMP ineffective. The available grades in the area are generally 2% or higher, limiting the application of this type of control. However, some lot-level controls, such as downspout disconnection are applicable to all areas, while others, such as filter strips adjacent to open space areas and grassed swales adjacent to suitable land uses have limited application. The use of infiltration-enhancing measures in addition to the use of infiltration trenches should be examined at the functional servicing plan stage when additional site-specific information and detailed design issues will allow a greater potential for implementation.

The stormwater management criteria and recommendations for the Sharon settlement area are summarized in **Table 10-4** below.

Table 10-4 – Sharon Recommendation Summary

Quantity Control	Water Quality	Water Budget	Best Management Practices
Post development flows to be controlled to pre-development peak flow rates ("post-to-pre"). Unit-flow rates as summarized in **Table 4-42** are to be applied for specific drainage areas in Sharon.	Water quality is to be controlled to Enhanced levels (i.e. 80% TSS removal). A required phosphrous removal rate of 9.9 kg/year/ha is required for the Sharon settlement area.	A required infiltration rate of 3788 m^3/ha is required for the Sharon settlement area.	It is recommended that the possibility of infiltration measures such as infiltration trenches, be examined before being implemented.

It should be noted that all requirements of the SWM guidelines should be met. The SWM guidelines can be found in **Section 12.1.4**.

Preferred SWM Strategy

Based on the above, the preferred SWM strategy for Sharon is the *Traditional SWM with BMP Implementation Strategy* in combination with *Traditional SWM with Urban Retrofits Strategy*. Retrofit opportunities are further discussed in **Section 7.0** and illustrated in **Figure 4-11**. Where applicable, it is recommended to provide BMPs in areas where soils and groundwater levels permit on a future development basis. A figure of the constraints and opportunities for the implementation of BMPs located within Sharon is provided as **Figure 4-11**.

10.1.5. Green Lane Expansion Areas

General

The Green Lane Expansion Area is designed to accommodate the growth of the Town of East Gwillimbury by providing appropriate employment and commercial areas. Existing conditions have designated this area as primarily agricultural and some rural residential.

There is currently only one (1) SWM pond in this area that is meeting Enhanced criteria. It is recommended that as growth continues, additional SWM ponds be considered to service the highly impervious areas. Only one (1) major waterway exists in the employment area with no identified erosion concerns. As development increases, runoff volume will increase and stream bank instability may occur. It is recommended to maintain a buffer zone of at least 15 m around the creek and uphold existing vegetation (or increase vegetation) to ensure adequate stability, infiltration, and phosphorus removal.

Four (4) SWM facilities are proposed as seen above in **Figure 4-12** and **Figure 4-13**. A further detailed study is recommended on a site specific basis to determine the location, size and number of ponds.

Quantity Control

As discussed in **Section 4.3.7**, quantity control should be enforced using "post-to-pre" criteria with the exception of the drainage areas outlined in **Table 4-42** in which unit-flow rates should be applied. Based on the amount of industrial and commercial area proposed in the Green Lane Expansion Area, developments should meet unit-flow rates to reduce peak flows entering the receiving watercourse. It is noted a detailed unit-storage / unit-flow study should be conducted on a sub-watershed level to confirm restrictions on watercourse discharge.

Quality Control

Stormwater quality control should be enforced using Ministry of Environment criteria and developments should provide 80% TSS Removal and Enhanced water quality levels.

As discussed in **Section 4.4**, stormwater quality control in terms of phosphorus control in the Green Lane Expansion Area should be enforced using criteria of a total phosphorus removal rate of 8.9 kg/year/ha.

Water Budget

As discussed in **Section 4.5**, in order to maintain the existing infiltration rates, future developments will require to maintain an infiltration rate of 5760 m^3/ha within the Green Lane Expansion Area.

Best Management Practices

Traditional BMP measures are recommended to be implemented in this area, and also innovative measures such as permeable pavement and green roofs. Urban BMPs as infiltration-enhancing measures in addition to the use of infiltration trenches and downspout disconnection should be examined when additional site-specific information is available.

The stormwater management criteria and recommendations for the Green Lane Expansion Area settlement area are summarized in **Table 10-5** below.

Table 10-5 – Green Lane Expansion Area Recommendation Summary

Quantity Control	Water Quality	Water Budget	Best Management Practices
Post development flows to be controlled to pre-development peak flow rates ("post-to-pre"). Unit-flow rates as summarized in **Table 4-42** are to be applied for specific drainage areas in the Green Lane Expansion Area.	Water quality is to be controlled to Enhanced levels (i.e. 80% TSS removal). A required phosphorus removal rate of 8.9 kg/year/ha is required for the Green Lane Expansion Area.	A required infiltration rate of 5760 m^3/ha is required for the Green Lane Expansion Area.	It is recommended that the possibility of infiltration measures such as infiltration trenches, be examined before being implemented.

It should be noted that all requirements of the SWM guidelines should be met. The SWM guidelines can be found in **Section 12.1.4**.

Preferred SWM Strategy

Based on the above, the preferred SWM strategy for the Green Lane and Employment Expansion Area is the *Traditional SWM with BMP Implementation Strategy* in combination with *Traditional SWM with Urban Retrofits Strategy*. Retrofit opportunities are further discussed in **Section 7.0** and illustrated above in **Figure 4-12** and **Figure 4-13**. Where applicable, it is recommended to provide BMPs in areas where soils and groundwater levels permit on a future development basis. A figure of the constraints and opportunities for the implementation of BMPs located within the Green Lane and Employment Expansion Area is provided above in **Figure 4-12** and **Figure 4-13**.

10.1.6. Rural Areas

The rural areas reside outside the above mentioned settlement areas in the Town of East Gwillimbury and are not part of the central growth area. There is no development proposed in this area, therefore land use will remain the same. In addition, approximately 75% of the Town is within the Oak Ridges Moraine and Protected Countryside. If the Town decides to grow further and develop into these areas, site specific studies are recommended. The implementation of rural retrofit opportunities as identified in **Section 8.2.5** should also be investigated.

Similar to the restrictions mentioned above, areas such as well head protection areas, high aquifer vulnerability, poor draining soils, and floodlines are all present in the rural areas. There is also land within the Oak Ridge Moraine that will have further restrictions on development according to the Oak Ridges Moraine Policies. It is noted that funding is available for rural retrofits as explained in **Section 12.4** and it is recommended that the Town investigate opportunities to retrofit rural areas on a site specific basis in the future.

10.2. Preferred Alternative Recommendation Summary

A summary of the recommendations presented in **Section 10.1** based on the preferred alternative for each settlement area was developed and listed below in **Table 10-6**.

Table 10-6 – Preferred Alternative Recommendation Summary

Settlement Area	Preferred Alternative	Recommended BMPs* (where appropriate)	Rationale
Mount Albert	Traditional SWM with BMP Implementation Traditional SWM with Rural Retrofits	Rural BMPs: Livestock fencing Buffer strips	Very small amount of growth Rural area will be maintained Within Oak Ridges Moraine
Queensville	Traditional SWM with BMP Implementation	Downspout disconnection Infiltration trenches Grassed swales	Proposed residential area Very small existing urban area

Settlement Area	Preferred Alternative	Recommended BMPs* (where appropriate)	Rationale
Holland Landing	Traditional SWM with BMP Implementation Traditional SWM with Urban Retrofits	Downspout disconnection Infiltration trenches Bioretention Rainwater harvesting Vegetated filter strips	Moderate amount of growth of residential and commercial Retrofit existing urban infrastructure where appropriate
Sharon	Traditional SWM with BMP Implementation Traditional SWM with Urban Retrofits	Downspout disconnection Grassed swales Vegetated filter strips	Moderate amount of growth Retrofit existing urban infrastructure where appropriate Few BMPs can be implemented due to poor infiltration
Green Lane Expansion Areas	Traditional SWM with BMP Implementation	Green roofs Infiltration chambers Permeable pavement Rainwater harvesting	Proposed commercial / industrial area Small existing urban area

*Recommended BMPs are based on settlement area specific conditions

10.3. Overall SWM Recommendations

Future SWMFs will be designed to MOE standards:

- Stormwater Quality Control: Enhanced – 80% TSS removal, 80% TP removal;
- Stormwater Quantity Control: Post-development peak flows to be reduced to pre-development levels for all storm events up to and including the 100-year storm. Unit-flow rates are to be applied for specific drainage areas requiring overcontrol to meet pre-development peak flows;**
- The Regional Storm should be controlled to the pre-development peak flow rate level *if* noted in the subwatershed study (LSRCA Technical Guidelines for Stormwater Management Submissions, November 2010);
- Site specific erosion control and detention time calculations based on individual fluvial assessment of the receiving stream (i.e. 24hr, 48hr, 72hr, etc.);
- Future developments will follow the guidelines as outlined in the Lake Simcoe Protection Plan (LSPP);
- BMPs will be implemented where applicable to establish a treatment train approach (i.e. source, conveyance and end-of-pipe treatment);
- Where opportunities exist, implement enhanced vegetation for shading, bottom draw outlets, cooling trenches at SWMF locations to reduce stormwater temperature;
- Where opportunities exist, reduce phosphorus discharge, improve infiltration and reduce erosion potential within settlement areas and expansion of settlement area boundaries;

- Where opportunities exist, implement rural retrofits for applicable areas outside of existing settlement boundaries; and,
- Proceed with retrofit opportunities and maintenance operations of select SWM facilities as identified by the LSRCA and the SWM Master Plan.

** It is recommended that an investigation regarding the implementation of detailed unit flow criteria should be conducted in the future for the East and West Holland River subwatersheds to establish a reduction of peak flows.

11.0 Public Consultation

11.1. Consultation Activities

In order to fulfill the requirements of a municipal class EA, several opportunities were given to general public, residents, agencies, and interested stakeholders for learning, sharing and responding to the project. The Municipal Class EA requires the Proponent to undertake two (2) mandatory points of public contact during Phase Two (Alternative Solutions). The Project Team has exceeded the mandatory number of public contacts, with the following opportunities for comment provided:

- Notice of Commencement;
- Notice of Public Information Centre;
- Public Information Centre; and,
- Notice of Completion.

11.1.1. Notice of Commencement

The Notice of Commencement was prepared and distributed to stakeholders and review agencies between December 20, 2010 and February 9, 2011. In addition, the notice was posted on the Town's website under "Our Town News". The notice informs stakeholders of the SWMMP being initiated in the Town and the study area that may be affected. The notice provides background information including the purpose, objectives and process. It also notifies the public about the consultation process consisting of one (1) Public Information Center (PIC) and the Public Education Campaign in place and gives locations of where further information can be found. Furthermore, the contact information for the Town's Project Manager and Cole Engineering's Project Manager were made available to the public to engage any initial feedback on the project.

A copy of the Notice of Commencement is provided in **Appendix M**.

11.1.2. Notice of Public Information Centre

A Notice of PIC was prepared and posted on the Town's website under "Our Town News". A copy of the Notice of PIC is available in **Appendix N**. The notice provided a description of the project, provided the details of the PIC, and included a request for comments and input. Contact information was provided for the Town's Project Manager and Cole Engineering's Project Engineer was also provided to encourage the submission of comments.

11.1.3. Public Information Centre

One (1) Public Information Centre (PIC) took place during the project. The PIC was held on March 3, 2011. It was attended by six (6) people mostly consisting of Town council and staff. The Project Team including representatives from Cole and the Town were in attendance to answer any questions that participants had.

The PIC presented the following elements:

- Study Overview and Background;
- Problem / Opportunity Statement;
- Overview of the Municipal Class Environmental Assessment Process;
- Alternative Solutions Being Considered; and,
- Next Steps.

The display panels presented at the PIC can be found in **Appendix O**. The PIC sign-in sheet and comment form are enclosed as **Appendix P**. It is noted that no comments were received as a result of the PIC.

11.2. First Nations Consultation

A letter and Notice of Commencement was sent to the Consultation Assessment Coordinator with Lands, Resources and Consultations at Métis Nation of Ontario. The project notice is currently being reviewed by the community. The impact that this statement may have could restrict the implementation of BMP measures on certain lands. It is expected that these impacts will be minor. A letter received from Indian and Northern Affairs Canada is included as **Appendix Q**.

11.3. Consultation with LSRCA

An initial meeting was held with staff of the LSRCA on January 14, 2011. The purpose of this meeting was to assess LSRCA approval requirements for the Lake Simcoe Protection Plan and future permits to be acquired during the Master Plan EA process.

The meeting minutes which provide preliminary comments on the Master Plan EA, which can be found in **Appendix R** with key points summarized below:

- LSRCA agrees with the intent of the EA process;
- LSRCA requires the SWMMP to follow the requirements of the Lake Simcoe Protection Plan; and,
- LSRCA prefers the development of the SWMMP to follow the Municipal Master Plan EA Process with regards to alternatives and public consultation.

11.4. Consultation with the Ministry of the Environment

A covering letter and the Notice of Commencement were sent to the Ministry of the Environment (MOE) on February 9, 2011. A letter was received from the MOE, dated March 8, 2010, confirming their requirements and suggestions for the EA process. This letter is included in **Appendix S**.

12.0 Implementation

12.1. Policy Considerations

12.1.1. General

As part of Policy 4.5 SA of the LSPP, recommended policies and SWM standards are required for future developments within the Town. Policies examined are discussed below and future SWM guidelines are discussed in **Section 12.1.4**.

12.1.2. Road Salts

An imminent concern in regards to the degradation of water quality is the accumulation of road salts within surface water. The CEPA defines road salt containing chloride as toxic, and therefore need to be managed in order to protect the Town's drinking water and aquatic life. Analysis of the Lake Simcoe Watershed indicates that chloride levels have remained constant or increased in most subwatershed and with the expect growth may further increase. It is recommended that the use, storage, and application of road salt and the disposal of snow be conducted in accordance to the Code of Practice for the Environmental Management of Road Salts (*Environment Canada 2004*). In reference to road salt application timing, schedules can be modelled after the Region of York or the Code of Practice. Alternatives to road salt should be explored such as the use of sand. It should be noted that when sand or other sediments are used, road sweeping is necessarily to be completed in a timely manner to avoid said sediments being carried into local watercourses. The monitoring of road salt usage requires a separate study to determine the best practices for the Town's need.

12.1.3. Water Temperature

The combination of warmer runoff from impervious areas and reduction in groundwater infiltration can produce severely elevated temperatures in the receiving streams, which can contribute to reductions in dissolved oxygen and create conditions outside of the thermal tolerance limits for desirable fish species and other aquatic life.

Chapter 4.4 of the *MOE SWMP Design Manual* states that "an increase in stormwater temperature is inevitable if an area is developed (i.e. urbanization causes stormwater temperature increases). This observation is based on current development practices." Mitigation by way of cooling can be provided if surface water is to be released on lawns or pervious areas before released from the site. In addition, subsurface trench outlets (such as those recommended in **Section 8.2**) has been suggested by MOE (Chapter 4.4) as a technique which reduces stormwater temperature. It is recommended that stormwater be discharged through underground trenches or onto pervious surfaces, where practical, before being released into watercourses. In addition, opportunities to implement SWM pond bottom draw outlets, cooling trenches and enhanced vegetation for shading be investigated for the reduction of stormwater temperature in future developments. It is noted that further analysis regarding the increases / decreases in stormwater temperature may be required during the functional design stage to accurately assess the changes in stormwater temperature as a result of development.

12.1.4. SWM Guidelines

As stated in **Section 10.3**, the overall SWM guidelines for the Town should be as follows:

- Future SWMFs will be designed to MOE standards;
- Stormwater Quality Control: Enhanced - 80% TSS removal, 80% TP removal;
- Stormwater Quantity Control: Post-development peak flows to be reduced to pre-development levels for all storm events up to and including the 100-year storm; **
- Site specific erosion control and detention time calculations based on individual fluvial analysis of the receiving stream (i.e. 24hr, 48hr, 72hr, etc.);
- Future developments will follow the standards as outlined in the Lake Simcoe Protection Plan (LSPP);
- BMPs will be implemented where applicable to establish a treatment train approach (i.e. source, conveyance and end-of-pipe treatment);
- Where opportunities exist, implement enhanced vegetation for shading, bottom draw outlets, cooling trenches at SWMF locations to reduce stormwater temperature;
- Where opportunities exist, reduce phosphorus discharge, improve infiltration and reduce erosion potential within settlement areas and expansion of settlement area boundaries;
- Where opportunities exist, implement rural retrofits for applicable areas outside of existing settlement boundaries; and,
- Proceed with retrofit opportunities and maintenance operations of select SWM facilities as identified by the LSRCA and **Appendix L** of the SWM Master Plan.

It should be noted that although “post-to-pre” stormwater quantity control criteria is recommended for future developments, this level of control may not reduce flows in the watershed to pre-development levels as per the hydrologic analysis in **Section 4.3. It is recommended that unit-flow rates be applied for areas requiring overcontrol to meet pre-development peak flow rates. An investigation regarding the implementation of detailed unit flow criteria should be conducted in the future for the East Holland and West Holland River subwatersheds to establish a reduction of peak flows.

12.2. Public Consultation / Education

It should be noted that SWM can be more effective with the addition of a public education program. A program should be focused on informing residents and businesses about the use of best management practices and low-impact development measures. The LSRCA is committed to continuing community and public outreach to engage the communities and encourage their participation in developing the future implementation plans. The LSRCA currently runs workshops and other outreach programs that the Town could use as a foundation to an education program. Moreover, The Town can model programs after those of The Region of York, such as their Water for Tomorrow Website or their Rain Barrel program to assist homeowners in reusing stormwater in their gardens.

12.3. Recommended Amendments to Official Plan

There are no current amendments to the Town consolidated OP 2031 that have been identified while carrying out this SWMMP.

12.4. Sources of Funding

The Ontario Soil and Crop Improvement Association in partnership with Agriculture and Agri-Food Canada, Ontario Ministry of Agriculture, and Food and Rural Affairs have developed a four (4) year program aimed to help farmers adopt Best Management Practices in four (4) main areas: environment and climate, food safety and traceability, business development and biosecurity. The Canada-Ontario Farm Stewardship Program will provide information, training, workshops, technical advice, as well as cost-sharing opportunities. Farmers can receive aid in proper manure and milkhouse waste storage, stream ditch and floodplain management, wetlands and wildlife ponds and soil management. Applications for the final year of funding will come up in November 2011, but it is highly encouraged to contact a local representative as soon as possible.

Further information regarding this funding program is available on the Ontario Soil and Crop Improvement Association website (http://www.ontariosoilcrop.org/default.htm).

LSRCA also has a similar program that provides landowners with funding and technical assistance for environmental projects on their land. LEAP (Landowner Environmental Assistance Program) can cover up to 100% for projects such as planting trees and shrubs, managing manure, controlling cropland erosion, and upgrading SWM ponds. Applications are made on an individual project basis usually by the landowner. Staff members are available to answer any questions regarding the planning and application process and it is recommended to contact the local stewardship representative before an application is submitted.

Further information regarding this funding program can be found on the LSRCA website (http://www.lsrca.on.ca/leap). Note that in the past this program has been very popular so it is recommended that applications be submitted early in the year.
